GEORGE WEBB.—Gen. George Webb, who died in Johnstown, Pa., October 9th, was born in Muncy, Lycoming County, Pa., November 4th, 1828. He taught school and educated himself in civil engineering. In 1850, he went to the lead mining district of Wisconsin. About 1852, he surveyed the northern boundary of that State for the government. The district was a vast wilderness, and he suffered great hardships. From 1856 to 1860, he was City Engineer of Dubuque, Iowa. In 1860, he negotiated with Jefferson Davis for the building of levees on the Mississippi, but, the war breaking out, he gave up all contracts and entered the Union army as captain of a company from Lycoming County. From 1862 to 1872, General Webb was Chief-Engineer and General Superintendent of the Catawissa Railroad, and lived in Williamsport during this time. He was also Chief-Engineer of the Baltimore & Potomac road, and constructed the large tunnel under Baltimore. In 1872, he was appointed Assistant General Manager of the Pittsburg, Cincinnati & St. Louis Railroad, and great credit has been given him in bringing that road to its present high standard. In 1874, he was appointed to the same position on the Pittsburg, Fort Wayne & Chicago Railroad. In 1875, he was appointed General Agent for the Cambria Iron Company. He had full control of all the tests of steel made by this company for the Brooklyn Bridge.

GOLD IN THE PROVINCE OF MINAS-GERAES, BRAZIL.

It was the discovery of gold which, according to Prof. A. de Bovet, of the Ouro-Preto School of Mines, first attracted people to the Province of Minas-Geraes in the beginning of the seventeenth century. Since then, it may be said that the working of gold ores has continued uninterruptedly, though with varying activity. Compared with what was done toward the close of the last century, this industry is to-day falling off, although this can not be attributed to the exhaustion of the deposits. They are far from being worked out. They may be classed under three general types, the pyrites veins, quartz veins, and itabirites. In the quartz veins, the mass of the deposit is quartz in which are found irregularly disseminated crystals of iron pyrites and particles of gold, generally coarse. Their richness is essentially irregular, while the pyrites found in them is also scattered irregularly and in pretty large crystals. In what has been called the pyrites veins, the mass of rock is formed of quartz and pyrites, the latter, however, predominating. The mixture is very fine, differing very much from the rock taken from the quartz vein. Arsenical pyrites forms the mass, iron pyrites being present only in small quantities. The gold in these veins is not found in scales or coarse grains, but in an extremely fine state; so that it is very difficult to pan out any gold. Instead of being irregularly disseminated in the mass, as in the quartz veins, the gold in this class of deposits is, on the contrary, distributed throughout, though with remarkable regularity; and the grade, though low, is approximately the same in different parts of the deposit. These veins are both true fissures clearly cutting through the country-rock, as at Morro-Velho, and as beds at Pary and at Passagem. Granites and gneiss form the lowest rocks of the province, above which lie schists, followed by quartzites and itabirites, which occur in two forms, as a solid rock, called "*pedra de ferro*," and a friable rock which has received the name of "*jacutinga*." The quartz veins are found both in the gneiss and later formations, while, so far as is known, the pyrites veins do not cut through the quartzites or the itabirites. The famous Morro-Velho vein cuts through the schists, while the bedded vein at Pary lies upon the gneiss. Where the veins have cut through or traversed permeable rocks, an impregnation of these rocks has taken place. This is not the case with the pyrites veins, which cut through the hard and compact schistose rocks. It holds good, however, for the quartz veins when passing through deposits of *jacutinga* and the hard quartzites, upon the cleavage surfaces of which gold is found. In the vicinity of Morro Prato, a considerable deposit of *jacutinga* has been worked by an open cut, wherever quartz veins have passed through it, the workings exending from 150 to 250 feet from the hanging and the foot-walls of the vein. The gold found in these deposits is coarse and very irregularly distributed. At some points, these itabirite beds have proved fabulously rich, while over a great extent they are absolutely barren. This class of deposits, it will be noted, is intimately connected with the quartz veins; still it is important enough because of the enormous development of the workings which it has given rise to, to consider it a third type of auriferous deposits. There seems little doubt that the gold in them has been derived from the quartz veins, its character being exactly the same, and being accompanied very frequently by pyrites. The quartzites, like those of Pary and Passagem, on the other hand, show a distribution of gold very similar to that of the Morro-Velho vein, for instance, and therefore it is probable that they have no connection with quartz fissure veins, but rather with pyrites veins.

As elsewhere, the alluvial deposits first attracted the attention of the miners and were rapidly exhausted. They were followed by the working of the itabirite beds; and it was only at a later date that the working of the vein deposits was begun. The large amount of capital required for such undertakings led to a transfer of operations from the hands of the native population to foreign companies, principally English organizations, which introduced new processes and worked with varying success. To-day, the few important mines working are in the hands of English companies, the Morro-Velho, Pary, and Morro de Santa Anna, and the total product of the province is little more than the combined yield of these enterprises. There are a few individuals who put up a small stamp-mill and work with a few men. They have not in view the working of their mines, but seem intent only upon holding their claims until the time may arrive when they can sell out to a foreign company. Generally, they have exorbitant ideas as to the value of their property, and this may account for their lack of enterprise. A description of gold mining in the province may therefore be limited to an account of the three great English companies already mentioned.

THE MORRO-VELHO WORKINGS.

The deposit worked at Morro-Velho is a pyrites vein, the ore being a close mixture of fine grains of quartz, arsenical pyrites, and iron pyrites, with occasional patches of copper pyrites, calcspar, and siderite. The vein, which is almost vertical, cuts through the schists, coursing from east to west. It is very narrow, but has a chute running down at an angle of forty-five degrees, with an average thickness of twenty-five feet and a length on the vein of 200 feet. It is this part of the vein which is worked. The first opening on the vein was abandoned on account of a fire in the timbering which led to caving. Under it, a sufficient thickness of ore was left to form a solid roof, and below it the workings were again taken up, being opened by two pits placed in the south wall of the vein. The workings are carried out without any headings or any gobbing, the whole of the ore being extracted and an open space left above. In this manner, an immense underground chamber has been left open 650 feet deep, 300 feet long, and 25 feet wide. Though the walls are solid, such an opening could naturally not be expected to stand, and therefore timbering on a grand scale is put in. In one year, six thousand cubic feet of timber were put into the mine. In this manner, it has been possible to reach a depth of 1900 feet. The water is pumped out with the aid of a wheel more than fifty feet in diameter, while the hoisting is done by a wheel of about the same dimensions. Dynamite is used for blasting, the holes being drilled by hand. Trials with rock drills have not, it is said, given satisfactory results. The total quantity of ore extracted in 1880 was 63,684 tons in 310 working days. The ore is first broken and sorted. It is then delivered to a stamp-mill and passed over buddles, the concentrates going directly to amalgamation. The

tailings are ground in arrastras, and, after going over a second set of buddles, yield concentrates for amalgamation and a large quantity of poor tailings. The larger part of the latter is carried off by the water and lost. A small quantity is retained to be worked when a practical process has been found to extract the little gold it contains. The concentrates are amalgamated in barrels, the amalgam being collected with mercury, while the tailings go to the buddles, the concentrates of which return to the barrels, while the tailings are taken to arrastras to be treated over again. There are 126 stamps, run by five wheels making from 56 to 67 drops a minute, and crushing per day 171 tons through a very fine sieve. The amalgamation is conducted in sixty Freiberg barrels, into which are charged from 1700 to 2000 pounds of ore and from 45 to 50 pounds of mercury. It takes twenty-four hours to complete a charge. The Morro-Velho ore is poor, the average being thirty grams per metric ton. Out of one lot of 162·5 tons, containing 4·8756 kilograms of gold, the first buddles under the stamps catch 3·604 kilograms in 9·144 tons of concentrates. Out of this, 3443 grams are obtained in the first amalgamation, and by the second working the rest is recovered, with the exception of 12 grams lost in the tailings. In the material from the first buddles and from the arrastra buddles, are obtained 160 tons of tailings containing 1420 grams of gold. Of this, a sufficient quantity is saved to reduce the loss to 25·4 per cent. Though this loss may be great, it is not high when it is considered how difficult it is to treat an ore in which the gold is in so fine a state that it is never visible to the naked eye, and can not be shown in the pan. It is very possible, besides, that a certain quantity is not in the metallic state and therefore escapes amalgamation. The Morro-Velho Company is continually carrying on experiments to extract the gold from tailings saved. Mr. De Bovet holds that it is not good practice to attempt to improve the yield by diverting attention exclusively to these tailings which only contain twelve grams per ton. He believes that it would be better to try to improve the other parts of the process, to direct the main efforts to the ore extracted from the mines, and not to the deposits of tailings. He advocates a closer classification for the buddles, and believes that roasting would facilitate the present operations. The labor question is one which is now seriously embarrassing the company, and coolies are to replace the slaves. In 1880, the profits of working 64,000 tons were £63,000 sterling, against £78,000 in 1879 and £103,000 in 1878, the dividends distributed in 1880 amounting to twenty-five per cent. In 1880, the mines employed 90 Europeans and 1211 Brazilians.

THE PARY WORKINGS.

The Santa Barbara Company is working at Pary a bed of iron pyrites, mispickel, and quartz, dipping at 45 degrees east, with a thickness of from 6½ to 8 feet. Its contents vary considerably. At some points, the vein seems divided in two parts, the upper being almost exclusively composed of quartz, hornblende, garnet, and mica, being barren and the lower part quartz and pyrites, containing gold and being similar to the Morro-Velho ore. At other points, the two rocks are mixed from the foot-wall to the hanging-wall. The deposit crops out on the side of the hill on the left bank of the Rio San Francisco, and at a few feet above the level of the river a long tunnel has been driven in. Above the level of this tunnel, all the ore has been removed, and the workings now are below it. The mine makes a little water, which is easily pumped out. The ore is broken and sorted by women, and the pyrites sent to stamps driven by water-power. There are four mills having an aggregate of 51 stamps, crushing per day about 38 tons of ore. The pulp is run over buddles, and is amalgamated in Freiberg barrels, yielding about 12½ grams of gold per ton. The average grade of the rock does not seem to be known. Work at these mines is considerably hampered by lack of water, and it is the intention of the company to provide it by a long ditch.

THE MORRO DE SANTA ANNA WORKINGS.

The workings of the Don Pedro North Del Rey Company are in a deposit of *jacutinga* of a very friable character, so that it is not necessary to crush it. The gold is irregularly disseminated, being in small grains. It seems to occur in pockets of great richness, which are, however, limited in extent. There appears to be no system whatever in the workings, which are simply a blind groping after the rich streaks. The only guide is the pan, samples being taken repeatedly each day from the workings, which are tested by panning. The mine naturally requires very extensive timbering, and the quantity of water is very large, while on the other hand, the power available is limited. In spite of the expense which these conditions entail, work has been going on with varied success, passing through extraordinary returns which are out of proportion to the yield for such an ore as the Morro-Velho. These bonanzas are followed by times of absolute failure, and it is a crisis of this kind that the mine is now passing through. The greatest difficulty encountered is the question of drainage. Formerly, the pumps were worked by a water-wheel, and when increasing depth made this means insufficient, another method had to be sought for. Only a small quantity of water for power was available, but it is under a high head. Therefore, a large iron wheel, sixty feet in diameter, was put up. The mine is opened by a long tunnel, ending in two inclined planes dipping at 28 degrees. Into one of these planes, the pump-rods were put in. This rod from the wheel to the pumps is in all 4560 feet long and weighs 45 tons. The cost of this enormous mass of iron brought from England may be imagined. Whether it was that the axle of the wheel was too weak or its spokes poorly attached, it was found that it would not work, and after a few attempts it had to be stopped and the mine was drowned out.

FURNACE, MILL AND FACTORY.

The Pratt Coal and Iron Company was organized at Birmingham, Ala., last week, by the consolidation of the Pratt Coal and Coke Company and the Birmingham Coal, Coke, and Iron Company. The new company takes possession of all the property of the concerns of which it is the successor, assuming their liabilities. The lands comprise about 75,000 acres, of which one half, that belonging to the Birmingham Company, is undeveloped. The paid-in capital of the new concern is $1,500,000. The following officers were elected at a recent meeting: Enoch Ensley, President; J. C. Neely, Vice-President; J. H. Smith, Secretary; J. C. Radcliffe, Treasurer; and W. L. Gude, Superintendent. It is believed that the proposed issue of $800,000 of bonds, which the stockholders will consider at their meeting on the 1st of November, is for the purpose of providing funds for building blast-furnaces near Birmingham.

T. C. Snyder & Co., manufacturers of iron roofing, at Canton, O., report increasing business. This firm is now manufacturing what is known as "calamined iron." The sheets are coated by a new patent process, which causes the iron to become coated with a material that is said to withstand sulphuric acid and all deleterious substances, and also solders better than tin or galvanized iron. The finished calamined iron resembles galvanized iron, and is said to be indestructible.

The Arizona Copper Company, owning the Clifton and Longfellow mines, Clifton, Arizona, has ordered of Fraser & Chalmers the following machinery: Three furnaces, 42 inches diameter, with all slag-pots, carriages, and bullion-pots. Three No. 6 Baker blowers. One No. "C" Comet crusher. Two Blake crushers. Three Leffel water-wheels. One upright boiler. Stillwell & Bierce heater and lime-catcher, pump, car irons, scales, furnace tools, roofing, iron blast gates and pipes. Two tubular steam-boilers, 60 inches by 16 feet, and accompanying machinery, amounting in all to about seventeen car-loads.

The Lackawanna Iron Company has started a remodeled spiegel furnace at Newark, which is doing excellent work. They closed the top and the front, and put in a Cooper stove which carries the blast up to 920 degrees at the stove. They blow through five 2¾-inch tuyeres and one small one above the front, the pressure of blast ranging between 6½ and 7½ pounds. The furnace is 34½ feet high and 8-foot bosh. Formerly, in blowing in, the furnace would make gray iron the first few days, not coming up to the regular grade of spiegel until the eighth day. With the remodeled furnace, spiegel was produced at the very start, and came up to 20 per cent metal on the third day. They get more gas and more oxide of zinc, approximately 15 per cent of the weight of the pig. The production now is eight tons per day, and it is expected that when running full it will average ten tons, against 7½ tons formerly. Mr. G. C. Stone has charge of the furnace.

The Jefferson Iron-Works, at Steubenville, which have been making extensive repairs about the mill, factory, and furnace the past three months, have resumed operations.

The Saucon Iron Company has closed its iron mines, and will blow out its furnaces. Low prices are said to be the cause of the suspension.

The rolling-mill of the Hollidaysburg Iron and Nail Company, which has been idle for about two months, is now running on full-time. The mill was thoroughly repaired during the suspension.

The Chicago Automatic Steam-Engine Manufacturing Company has lately been organized, with a capital of $300,000, by Lyman E. De Wolf, John V. Colby, and Dennis O. B. Ladd.

The Bridgeport Brass Company, Bridgeport, Conn., is erecting a new factory 150 by 35 feet, three stories, and built of brick. This building is erected to accommodate the increasing business in the manufacture of electric light and telegraph wires.

Col. A. H. Leftwich has purchased the James River Iron-Works, four miles above Lynchburg, Va., for $75,000. He will turn the same into a nail factory. It is valuable property, and cost originally $296,000. It has not been worked for several years.

The Ordnance Bureau of the War Department has made a contract with the South Boston Iron Company for the manufacture of one of the Yates heavy rifle cannon for experimental purposes.

The Catasauqua *Dispatch* reports that the new blast-engines at the Crane Iron-Works have been tested and found to work well. The erection is not yet completed. The blast-engines of the company are repainting and getting in good order. The fire some years ago in No. 8 engine-house destroyed the wooden platforms, and when it was rebuilt, they were abandoned altogether. It has been found necessary to rebuild them, for the better security of the walls.

The Steelton *Reporter* states that the rail-mill for the month of September rolled 14,318 tons of steel rails of various patterns, being an increase of 3472 tons over the corresponding month of 1882. The production last week was 3619 tons of steel rails. The Bessemer mill last week produced 4436 tons of steel ingots. The tonnage for the month of September in the Bessemer mill was 17,210 *tons*, being an increase of 2152 tons over the corresponding month last year. The blooming mill cut out during the month of September 15,858 tons of blooms. The merchant mill will be put in operation as soon as the engines are completed. The engine on the lower train of rolls has been running all the week testing the rolls, which have been found to be in perfect order. The frog, switch, and interlocking department is running night and day to fill orders on hand and those constantly arriving. No. 5 furnace is again in full blast, and lately made the largest production in the history of the furnace.

The Pittsburg Bessemer Steel-Works, located at Homestead, Pa., were sold October 16th to Carnegie Brothers & Co., of the Edgar Thomson Steel Company. The basis of the sale is said to be $1,200,000.

The Union Steel Company has been incorporated at Springfield, Ill., with a capital stock of $4,600,000. This is the company organized to purchase the plant of the Union Iron and Steel Company. The date for the resumption of work at the mills is still indefinite.

The announcement is made officially by the Thomas Iron Company, of Hokendauqua, that two of its furnaces at Columbia have been blown out and two at Hokendauqua; in addition, two already idle will be blown out shortly. Another furnace at Hokendauqua, which has been in blast for five years, will probably be blown out soon.

It is rumored that the Allentown Iron Company will blow out its last working furnace.

The Cincinnati Cooperage Company has placed its order with the Lechner Manufacturing Company, Columbus, O., for chain conveyers, to be used at its works at Cincinnati, O. This company has also received orders for chain belting from the Colorado Machinery Company, South Pueblo, Colo.; F. W. Schroeder, Roca, Neb.; C. C. Warren, Waterbury, Vt.; and others, to be used for conveyers and driving purposes.

GENERAL MINING NEWS.

ARIZONA.

Governor Tritle, in his report on the progress and development of the territory, says that the territory can now claim a population of 75,000 people and the possession of over $20,000,000 in taxable property. The dangerous and disturbing elements which have been factors in checking progress are now well under control. In the last two years, exceptional development has been made in all industries, mining, grazing, and agricultural. Extensive railroad enterprises have been completed, and the affairs of the territory are in an exceedingly prosperous condition. The value of the gold and silver product for the year ended December 31st, 1883, is placed at $9,298,267, against $8,198,766 in 1881. A large quantity of rich ore and base bullion, which is estimated to amount to at least 10 per cent of the figures given, is not included in this valuation. The yield of copper in 1882 was about 15,000,000 pounds. The combined value of the silver and copper product for 1883 will be between $15,000,000 and $16,000,000.

COCHISE COUNTY—TOMBSTONE DISTRICT.

DEAN RICHMOND.—Work will be resumed shortly. A contract is to be made with the Woronoco Smelting Company.

EMPIRE.—Work has been resumed.

GIRARD.—At the 200-foot level, a four-foot body of fine chloride ore has been encountered, and a large quantity of fine-grade ore is hoisting to the surface. From a series of assays made, it appears that the averages were $200 in silver. At the 300-foot level, the ores are sulphurets, but equal in richness to those in the upper level.

GILA COUNTY.

OLD DOMINION.—Superintendent Thomas, of this company, at Globe, reports the August product from one of the Rankin, Brayton & Co.'s 30-ton smelters to be 403,810 pounds, an average daily yield of 13,460 pounds, bullion running 99 per cent.

PINAL COUNTY.

RAY COPPER.—Under date of October 9th, J. M. Haskell writes to Mr. L. Zeckendorf, secretary and treasurer of the company, as follows: I visited the Ray Copper Company's property on the first instant, and remained there some days. I was very much pleased with the developments. There have been 500 feet or more of tunnel, winzes, and drifts run since my last visit, and nearly every foot in ore, native copper, carbonate, glance, and oxides. There is a large amount now in sight, enough to run a year or more, with good reduction-works, to say nothing about the rest of the properties where there are thousands of tons that will work in with the Ray ores. I also, while there, tested thoroughly the carbonate ore and native copper, both sheet and shot, and the concentrations were very satisfactory indeed, settling much better than I expected. There need be but a very little loss in concentrating—in fact, nearly nothing—and it will be possible to run the grade well up, say from 20 to 30 per cent. The native copper you can either melt or ship, as you may elect. I recommend starting a new shaft, which will, when down 50 or 100 feet, cut the vein where I believe it will expose a larger and better body of ore than yet found in the mine, and also will answer for the main working-shaft for at least 400 feet in depth. The property now is a settled fact. You can order concentrating-works and put your furnace in repair. The property will pay good dividends, when once the reduction-works are fairly running.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

The men are taking up the pump-column at the Lent shaft at the 1000-foot level, and a number of men have been discharged. For two or three months, the Bodie and Standard people have been negotiating with the view of sinking the Lent 200 feet deeper, and prospecting both mines on a level from it. This would give the Standard a depth of 1440 feet, and the Lent 1200 feet, the collar of the Lent being 240 feet lower than the Standard. A division of the expense would have made it comparatively light for each company, and, in fact, it would seem to be as sensible and economical a proposition as could be made. For some reason, says the Bodie *Free Press*, the plan seems, for the present at least, to have fallen through. The stopping of work on the 1000-foot level of the Bodie will not affect the extraction and milling of ore, as the latter is taken from above the 800 level. The ore for a week or two back has been of better quality than heretofore, and the bullion shipments have been larger. The appearance of the mine generally is better than it has been for some time back.

NEVADA COUNTY.

IDAHO.—The average output of ore is about 100 tons a day. The results of the working of the ore are entirely satisfactory.

EMPIRE.—The output continues steady and profitable. The mine gives employment in all its departments to 200 men. Outside of these, there are working in various parts of the drifts of the mine, and at the surface on small veins or feeders to the main vein, some thirty men as tributers.

CANADA.

PROVINCE OF ONTARIO.

A number of prospectors are at work in the county of Ottawa searching for galena deposits. Several very rich deposits of this ore have been recently found in this district.

COLORADO.

CHAFFEE COUNTY.

ALPINE SMELTER.—The smelter is about ready to blow in, and is already contracting for ore. Concentrating machinery and amalgamation tables will be added to the present plant.

CLEAR CREEK COUNTY.

CORRY CITY.—In driving the tunnel level west of the shaft, a streak of iron ore several inches wide was exposed which assays from 99 to 105 ounces in silver per ton. Seventy-five feet down the shaft, a cross-cut has been run eleven feet south toward the foot-wall, and is all concentrating material, which runs from 11 to 172 ounces. There is a three-inch streak in it which mill-runs over 100 ounces.

FREELAND MINING AND MILLING COMPANY.—The company has purchased the Dumont smelter, situated at Freeland. The company will not enter into possession before January 1st, 1884, previous to which a general clean-up will be made, and the works put in perfect repair. Alterations will be made and improvements added. It has already proved itself perfectly adapted to the smelting of the ores from the Freeland mine.

KOHINOOR & DONALDSON.—Five car-loads of machinery for the mill at the mouth of Fall River have been received. The machinery is in process of removal to that place, and will be put in operation as soon as possible. This mill, when completed, will be one of the largest in this part of the State.

PAY ROCK.—The mill is now running steadily double shift, and is consuming about thirty tons of dirt daily. The supply of water is sufficient, and the mill will probably run all winter.

DOLORES COUNTY.

LITTLE MAGGIE.—A shaft was started 120 feet from the mouth of the tunnel, and has been sunk 30 feet, in which distance 65 tons of first-class ore have been taken out and shipped to the Grand View smelter. This ore runs 68 ounces in silver and 40 per cent in lead. An equal amount of ore of lower grade has been reserved from this working, making 130 tons of ore from a shaft 30 feet deep. At the bottom of this shaft, a chamber has been cut, showing the vein to be 18 feet wide, with a solid ore-body 12 feet wide.

GILPIN COUNTY.

LITTLE EDDIE.—Drifts are extending east and west from the main shaft at a depth of 45 feet. The west drift is passing through quite an extensive body of ore, milling and smelting, the former varying in its yield from 2½ to 6½ ounces gold per cord, the average being 4 ounces. The smelting ore nets $40 per ton.

REPUBLIC.—The company's 25-stamp mill is well supplied with ore from the Pewabic mine, and is kept running steadily.

LAKE COUNTY.

CHRYSOLITE.—The new double-plunger Cameron steam-pump for the Iron incline has been received and put in position. The capacity is estimated at from 250 to 300 gallons a minute.

CUMMINGS & FINN.—Grant & Company will assume possession of this smelter November 5th.

DUNKIN.—The following statement, taken from the books of the company, shows the product of the mine from January 1st, 1883, to October 1st, $42,959; expenses during the same period, $18,047; profits, $24,912. Dividend paid, $10,000. Cash on hand October 1st, 1883, in New York, $6771; in Leadville, $8529. Total cash on hand October 1st, $15,300. The product of September amounted to $6113.29; the expenses to $2194.32.

FIRST NATIONAL MILL.—This concentrating mill, situated in Iowa Gulch, has been leased and will be started up.

HARRISON.—The new roasting-kilns recently erected at the works are partially completed and several of the stalls will be fired at once. The compartments are about ten feet square and six feet deep, erected in two parallel rows, with a flue between them, connecting with a stack 60 feet in hight. The compartments number sixteen or twenty. The ore to be roasted in these kilns is the sulphide mineral now produced by the Colonel Sellers and other mines of California Gulch. Quite a lot of this ore was found on the ground, which averages about forty per cent in sulphur. A layer of wood about twelve inches in depth, it is estimated, will start the sulphur in the ores to burning, and when this is once accomplished, the process will continue until completed.

IRON HILL CONSOLIDATED.—The mines during the month of September shipped 950 tons of ore. The product of the mines has shown a marked improvement in the average value per ton. The mines are all looking well. The new hoisting machinery for the Imes shaft is all in place and in working order. The shaft has reached a depth of 600 feet, penetrating the underlying limestone 200 feet. The intentions are to begin work at this shaft by drifting from the 400-foot level. It is at this station that a line of contact between the porphyry and limestone was intersected. The further exploration of the lower lime strata will, however, not be deferred any great length of time, and at an early day a pump is to be added to the plant, and the shaft, now containing considerable water, is to be cleared,

Digitized by Google

and sunk to greater depth, and levels driven on the mineralized seams already disclosed.

LITTLE PITTSBURG.—Work is to be started up immediately on No. 10 shaft of the Little Pittsburg claim.

LITTLE SLIVER.—The mine is worked principally with a view to exploration and development, and as a consequence the output is very light.

LUZERNE.—An important strike was made recently in this lode. The ore consists of sand and hard carbonates, and ocher, and to all appearances will prove very rich in silver, in addition to carrying an appreciable amount of lead. The location is isolated from working mines, being about midway between the Henriett and Chrysolite and Little Pittsburg mines, and opens up a section of territory heretofore universally condemned. The possibilities presented are therefore great, and it would not be surprising if this discovery led to the development of an ore-chute that will prove a great bonanza. The shaft has a depth of 175 feet, and was sunk to within a few feet of the ore-body last year, when the owners ran out of funds, and were forced to suspend work.

ROBERT E. LEE.—The mine is working from thirty to forty men, and shipping from twenty to thirty tons of ore a day, in addition to the shipment of dump material to the Leadville Gold and Silver Mining Company's mill. The general range of the ore is from 60 to 300 ounces to the ton, while small lots have been shipped assaying as high as 2200 ounces in silver. The first, second, and third-class ores are sold to the smelters, who work them in with the lead ores and the low-grade material to stamp-mills.

SILVER CORD.—During the month of September, the mine shipped 3700 tons of ore. The output of the mine has not yet been completely settled for, but sufficient is known to show an appreciable deterioration in the grade of ore. The mine is producing its customary amount. So states the Leadville *Herald*.

RED MOUNTAIN DISTRICT.

The mines and prospects situated along Lake Creek, above Twin Lakes, are doing well. A number of properties are shipping regularly, and several mills in this section are kept employed steadily. The ten-stamp mill at Everett's is running on Forest Queen ore, and is doing satisfactory work.

Among the mines working is the Lucky Strike, which is having the assessment-work done, and is looking much better than last year, when the annual work yielded a ton of ore running 473 ounces in silver. The vein is two feet in width, and is situated on Mount Ewing.

The Jeannette mine is worked, and is producing some fair ore, that is shipped. A cross-cut tunnel is driving by the Jack Pot lode.

PARK COUNTY.

SOVEREIGN.—This property is situated on the eastern slope of North Star Mountain, and embraces four locations aggregating 6000 feet on the old Harrington vein.. This lode attracted attention twenty years ago, and its large production and unusual wealth soon collected about it a large number of the early miners, forming the town of Montgomery. The vein has a width of from four to ten feet, is very regular, and possesses fine walls. Its course is nearly north and south, with a dip to the westward of about 75 degrees. The oxidation of the mineral extends from 25 to 35 feet below grass-roots, where the ores in their original condition are found. Below this line, the vein-matrix consists of copper and iron pyrites and quartz carrying gold and silver in profitable quantities. The ore is reported to range in value from $50 to $150 per ton. The development of the mine aggregates about 4000 linear feet of tunneling and shafting, thoroughly demonstrating the strength and permanency of the lead. Several of the tunnels have been driven in on the vein from 200 to 300 feet, the deepest showing a solid breast of mineral four feet in width, that numerous assays have proved to be worth about one hundred dollars per ton. Another tunnel shows three feet of solid ore, while other openings show from twenty to thirty inches of excellent pay mineral. The lower tunnel is in 306 feet, and will be continued until a length of 2500 feet is attained, which will open the vein 800 feet below the outcrop and highest workings. The operations of the mine being confined to opening it for a future production, the yield so far has been light. The dumps, it is estimated, have 3000 tons of pay-ore, to which additions are made daily as development-work advances. The shipments during the past season have been limited to small quantities of free-milling ore. Thirty days' work on this class of material, treated at a quartz-mill, yielded 360 ounces of gold, worth nearly $7000.

SUMMIT COUNTY.

HORN-SILVER.—A large body of high-grade mineral has been struck.

DAKOTA.

FATHER DE SMET.—The superintendent reports October 1st: At the mine, work is going along as well as usual, with no important changes to note in any of the ore-breasts. The Golden Gate south header shows up as well as ever; the face is all in ore that samples from $5 to $7. We begin breasting out across the ledge to-day. East cross-cut, third level, is making very good progress, and ought to strike the ledge soon. The face is still in slate, mixed up with small stringers of quartz, but of not much value as yet. The report for the week ended October 7th shows: Ore extracted from first level, 900 tons; second level, 700 tons; third level, 375 tons. Ore milled, 1975 tons. The Golden Gate east cross-cut, third level, is 86 feet, and the Golden Gate south header, second level, is in 58 feet. The superintendent writes October 4th, as follows: I herewith inclose Express Co.'s receipt for bar No. 168, containing 1189·65 ounces gold, the result of the clean-up of the mill for the last half of September. This makes a total of 1947·35 ounces for the month. I am afraid it will be impossible to keep these figures up right along, but will do the best we can and make the best showing possible. At the mine, every thing is about the same as usual. The faces of both cross-cuts and south header show no change since last report.

KING SOLOMON.—The personal property has been sold at Tigerville. The Black Hills *Index* says that this is the result of bad management.

IDAHO.

The *Times* reports that the current season on Wood River has been one of great activity, and the consequent results are becoming apparent in the increased yield of the mines. Notwithstanding the late date of the completion of the railroad to Hailey, and the corresponding resumption of active operations, the yield of the mines, concentrating-works, mills, and smelters, will be large, and, when the many obstacles that had to be overcome are considered, eminently satisfactory. The aggregate yield of the Wood River and Sawtooth region this summer will probably not fall short of $5,000,000.

BAVARIAN.—Some ore treated showed 90 ounces silver and 75 per cent lead. The vein of this recently discovered mine is about two feet wide.

COLUMBIA & BEAVER.—The second shipment since starting up the mill has been made.

DAVITT.—This mine has yielded $45,000 since the end of last April, when the company resumed work. Within the past three weeks, a new shaft was started on a vein entirely distinct from the Davitt. This shaft is down 50 feet, in ore all the way, which shows widest at the bottom, where a drift that is in 25 feet from the shaft shows the vein to widen all the way out, until it gets to be fully two feet wide in the face of the drift. This new vein or ledge can be traced on the surface for 800 feet.

MAYFLOWER.—The Salt Lake smelters have purchased 100 tons, and an arrangement for the sale of all the product of the mine has been concluded with the agent of the Kansas City Reduction-Works. As soon as that contract is ratified by the company, the shipments of Mayflower ore (which have been suspended since the Ketchum Works refused to buy any more of it at the rates then ruling) will be resumed.

MULDOON.—The mine has been shut down for the winter.

SILVER KING.—About $40,000 were produced in two months.

MEXICO.

A correspondent of the Mexican *Financier* speaks of mines along the Pacific coast between Alamos and Mazatlan as follows: Near Alamos, there are the Minas Nuevas, run by an American firm, which employs 150 men, works 10 stamps, a concentrator and roasting-furnace, heating apparatus, smelting-furnace, and refining furnace. From Agiobampo, distant 170 miles, freights rule from $2.75 to $5 a carga. From Mazatlan to Agiobampo, freights are $10 a ton by schooner; and from Guaymas to Agiobampo, $8 a ton. Also in this district, within six miles of Alamos, four mines are working a large force, and three in Aduana.

The Promentorio mine has a 30-stamp mill, a 30-ton water-jacket smelter, and employs about 500 men.

At Pochibampo, no mines are actively worked now; but as soon as cheap transportation is afforded, several veins of low-grade and rebellious ores will be available.

At Techibampo, a number of mines have steadily been working for three years. The best ores have been shipped to Europe at a great expense, the cost of hauling to Agiobampo being about $35 a ton, and in little schooners from there to Mazatlan, $10 a ton.

At Roricarichi, are extensive silver mines which ship 300 or 400 tons a year to England of picked ores. It costs $50 a ton to haul or pack this ore to Agiobampo, or $4 a carga to the reduction-works at Minas Nuevas. At these mines, they leave about ten tons of low-grade ore on the dumps for every ton of ore they ship.

At Chinipas, there are a number of low-grade mines, which are now useless on account of the high rates of freights.

At San Agustin, there are two very important mines not now worked because the owners have not the means to put in the machinery required.

At Talmarapa, there are about 1000 men working on high-grade ore, with 14 stamps now running, and more going in.

The Hurapa mines are equally important. They have ten stamps now running by water-power, and will soon have twenty more worked by steam.

In the State of Sinaloa, is the Cosalá District, one of the largest in all Mexico. Some of its magnificent mines have been worked for many years, and are still as promising as ever. The Estacata mine had a vein of three inches on the surface. It gradually widened and increased until, at the depth of 400 feet, a bonanza was struck, not so rich, yielding $200 a ton. This was about 50 feet wide and 300 deep, when it became narrower and tapered into the original width of the vein. A second bonanza was struck at a much lower depth, 30 feet wide of continuous ore, averaging $250 a ton. Thirty stamps are employed. There is a group of old mines, the Mammoth, Realito, La Estrella, Mina del Agua, and Bufa, worked by a San Francisco company, the Mexican Mining and Real Estate Company of Sinaloa. The Mammoth opens into a large body of quartz. Two shafts have been sunk 200 feet deep and 120 apart, with rich rock on all sides, averaging $80 a ton.

The Realito is on the side of a mountain, reaching a vein three feet wide by a tunnel 500 feet above the arroya. The mineral assays run high. La Estrella dips at an angle of 45 degrees, is about 65 feet wide, assays average $175. The Bufa and Del Agua are also valuable properties. The company working these mines has large reduction-works and a large estate in lands, about 80,000 acres.

The Golconda mine, of the Cosalá District, is a large body of fine gold quartz, easy of reduction, and worked by the usual process. The ore at a depth of 120 feet assays $300 a ton. Several shafts have been sunk from 300 to 500 feet apart, each striking the same lode and the same body of ore. This mine is situated on the Cosalá River, a tributary of the Flota, and within a mile and a half of the valley of Cosalá.

The Nuestra Señora is another old and celebrated mine which has produced millions.

The Barretras mine built up the town of Cosalá and was founded on its tributes.

Northeastwardly from Culiacan is the Guadalupe and Calvo District, with rich mines all around, among them the Yedras, owned by Clarence King's company, with 40 stamps and consuming from 5 to 8 tons of salt daily. The Guadalupe and Calvo mine, with ten stamps, takes three quarters of a ton of salt a day to work 15 tons of ore. The Mineral del Cuerro ore is free-milling.

At Galiana, several companies have recently been organized. The Aldama mine is now opening up, and the natives work scores of mines in a small way by arrastras. From this group, conductas charge one per cent for taking ore to Parral or Culiacan.

TLALPUJAHUA DISTRICT.

BORDA.—At this mine, they are making a new start at the northern end, and will cut the main vein at a depth of 50 or 60 yards.

CONCEPCION.—The July product of the mine was 7000 ounces of silver; in August, it increased to 13,247 ounces. The mine is producing from 250 to 300 cargas a week, there being 300 pounds to the carga. Up to June, the work cost at the rate of from $8 to $10 a carga. In July, it cost $4.25 a carga; in August, it cost, up to the 22d, $3.15 a carga; and the last week of August the cost was reduced to $2.85. It is thought that the cost can be reduced to as low as $1 a carga. The present cost of milling is $8.10 a ton of 2000 pounds, that is, with the small five stamps and three barrels now running; but if they had 50 stamps, the milling could be done for $4 or $5 a ton. The average of ore is 67 ounces to the ton, but the select ores go as high as $1800 to the ton, and very small amounts, $4000 or $5000 a ton. The actual depth of the mine, although it is an old one, is only 225 feet. The main vein is 8 feet wide. If the mine were worked with hoisting machinery and all kinds of improvements, the ore could be taken out at $2 a ton; but by having peones to carry it out on their backs, it costs four times as much, and of course low-grade ore can not be worked profitably.

MONTANA.

BEAVER HEAD COUNTY.

HECLA CONSOLIDATED.—The following statement shows the production from January 1st to August 31st:

Month.	Pounds lead.	Ounces silver.	Ounces gold.	Value in dollars.
January	419,416	41,651·80	2·293	$64,310.46
February	394,618	38,327·12	1·171	59,562.60
March	401,194	40,229·35	9·462	63,396.02
April	405,275	35,314·27	2·032	56,711.91
May	405,749	38,550·23	8·088	61,470.05
June	533,309	56,531·93	2·022	85,521.42
July	531,551	55,524·01	1·767	84,286.50
August	458,149	55,421·47	2·128	81,089.57
	3,549,252	361,580·18	29 963	$556,348.53

GALLATIN COUNTY—NEW WORLD MINING DISTRICT.

The district is situated at the head of Clark's Fork, bordering Wyoming, on the western spur of the Bear Tooth Mountains. The mineral belt is about eight miles wide, extending from the western slope of Miller to the eastern slope of the Henderson Mountains, and fifteen miles long, running from the Wyoming line, on the south, to Lake Providence, on the north. The veins are numerous, strong, and well defined in a porphyry and slate formation, trending north and

Digitized by Google

south, and bearing rich tetrahedral and cube galena ores. The country abounds in iron and lime for fluxing purposes.

REPUBLIC.—This company is the only one in operation. It is erecting concentrators and smelters with a capacity of 100 tons per day. The company owns several valuable claims which are thoroughly prospected, showing sufficient ore in sight to keep the works running for a limited number of years, and from tests made will yield from 55 to 60 ounces in silver and from 45 to 50 per cent lead.

LEWIS & CLARKE COUNTY.

BOSTON & MONTANA COMPANY.—The machinery for the additional works at the Gloster is now shipping. By the addition to the plant of sixty stamps, the company will have the pan amalgamating principle which has proved profitable in the gold mines of California. The machinery of twenty-four pans and twelve settlers is constructing by the Union Iron-Works, of San Francisco.

SILVER BOW COUNTY.

ALICE.—In the 100-foot level, the stopes are in a body of black sulphurets, which break off from the ledge in blocks and work and mill easily. The ore assays from 120 to 130 ounces. The west drift from the 800 has advanced 125 feet from the bottom of the winze, and the stopes are in 58-ounce ore. Prospecting is vigorously prosecuted at the face of the drift, to develop the extent and value of the vein. So far as developed, the ore-body in the lower level has been very satisfactory. The rock is fine-grained and carries less base than the ore from the upper levels, and, like the south vein, there is a great improvement in the quality of the ore as depth is attained.

ANACONDA.—The Dexter mill is running on free-milling ore from the Anaconda dump and running through 25 tons per day. The ore is from the waste-dump, and after sorting, produces from 14 to 16 ounces to the ton, which is worked at a profit under the improved appliances in use at the Dexter.

POLLACK.—Clark Brothers, of Walkerville, who are operating this property under a lease, have run a tunnel on the ledge from the east end of the claim which is now in 125 feet. A shaft is running which will intercept the tunnel 100 feet farther west, and another shaft has been started to the west and south. Both shafts and tunnel are in good pay, some of the ore assaying high.

TRAVONIA.—Much interest is taken in Butte in the development of this property, recently begun by W. A. Clark, from the fact that it was in this mine that silver-bearing quartz was first discovered in Summit Valley, and shipments to the Newark Refining-Works of the rich chloride ore from the Travonia first attracted the attention of outside capitalists to the camp. In 1875, twenty-five tons of ore from the west shaft were shipped to Newark, which returned over 300 ounces per ton, and in 1877 another shipment was made, which returned 136 ounces of silver and $6 gold. The mine has lain idle for many years until recently. A lot worked at the Colorado smelter recently yielded about the same return. The work at present is principally confined to development and exploration to determine the character and value of the ore-chutes. Very thorough work is done.

NEVADA.

ESMERALDA COUNTY.

COLUMBUS CONSOLIDATED.—All recent work in this mine has been followed by good results. The connection made between the new shaft and the Bonanza winze has proved to be of great advantage to the men working in the winze, as well as to those in the other parts of the mine. When sinking was resumed in this winze, it was down 83 feet. It has now reached a depth of 107 feet. The bottom shows streaks of very rich ore. It is intended to sink 25 or 30 feet farther, and then drift to the east and west on these streaks of ore. The prospect in this winze is very encouraging, and the work of sinking and developing will be diligently prosecuted. The cross-cut has a length of 33 feet, its face being in ground showing broken ledge-matter.

MOUNT DIABLO.

The drift from lower winze No. 2 has developed some ten inches of $40 ore. The stope from this winze shows improvement, and is giving considerable $60 ore. The stopes below the third level, near winze No. 1, are yielding a good deal of $50 ore. The stope above the west drift on the third level is giving some $40 ore from a wide ledge. A little rich ore is extracted from the second level near the center of the mine. The east and west drifts on the second level are giving considerable manganese ore of rather low grade. The intermediate, between the first and second levels, is turning out a good deal of $60 ore. The stope above the west drift from the Callison winze shows a rather stronger ledge in the west end. The center of the ledge shows but little of value, while the east end of the stope is giving some ore of high grade.

EUREKA COUNTY.

EUREKA CONSOLIDATED.—The recent development on the 1200-foot level has gradually improved. Other parts of the mine, all worked through the old shaft, have also brightened materially. The developments in the K. K. ground also continue with the most cheering results.

STOREY COUNTY—COMSTOCK LODE.

There is nothing of importance to report from the various mines. Work goes on as usual. The low water in the Carson River, however, prevents the mills from running to their full capacity. Mr. J. W. Mackey has recently been in Virginia City, and visited the Union Consolidated and adjacent mines. In an interview, he stated that he found the north end mines greatly improved.

NEW MEXICO.

GRANT COUNTY.

Until recently, very little has been heard of the Steeple Rock District, which is in the western part of Grant County, bordering on the Arizona line. The mineral belt is about two miles in width, the veins being true fissures, cutting the formation for miles in extent. The formation is principally porphyry, the ore being found in the quartzite ledges. The ore-body, of course, varies in width, but in some places where opened up has been found to be thirty feet wide, carrying principally gold, but also running well in silver.

LINCOLN COUNTY.

RITA.—The mine has about forty feet of development. A clean-up was lately made at Professor Glass's stamp-mill, from a run of eighteen tons of the Rita ore, which resulted in a nugget of gold weighing thirty-one ounces, valued at $20 per ounce, or $620.

SOCORRO COUNTY.

The product of the smelting-works at Socorro for the past month amounts to 10,000 bars of bullion. A third stack is building, when the monthly product will be $75,000 in bullion.

NORTH CAROLINA.

It is reported that the copper mines at Ducktown have been purchased by an English company from Williams & Black, of New York, for $600,000. The mines failed a few years since for $3,000,000. They are the most extensive in the South.

UTAH.

BOX ELDER COUNTY.

TRUE FISSURE.—The mine is producing regularly. A shipment made demonstrates that the ore is getting richer and better as depth is gained.

SALT LAKE COUNTY.

GERMANIA.—The smelter began shipping August 3d, and up to September 10th shipped fifty-six cars of bullion, 1,857,955 pounds, valued at $129,006.95. The white-lead product has been an average of one car per week of the value of $1500, and lead pipe the same amount, the product having been regular since June 1st.

UTAH COUNTY.

The mining outlook in the American Fork Cañon is very promising, although it must be admitted that the camp is rather slow in showing-up, says a correspondent of the Salt Lake *Tribune*.

The Live Yankee has a very large body of good ore in sight, but is working a small force.

The Silver Bell is working a force of ten men. A tunnel is driving to strike the ledge. The mine is shipping no ore, and probably will not ship any until the tunnel strikes the lower levels, where there is an abundance of ore in sight.

In the Silver Lake District, the Milk Maid is working 16 men, and ships from ten to fifteen tons of ore per week.

West of this property are the Good Hope and Olney mines, both in granite formation, and with shafts from 70 to 80 feet deep. These mines show fine ledges of quartz, assaying from 30 to 40 ounces in silver, from $3 to $10 in gold, and a very small percentage of lead. The gold quartz formation in the ledges of those mines is from one to three feet wide, and appears to grow richer as depth is attained.

WISCONSIN.

The discovery of a large bed of iron ore in the northern part of the State is reported.

PATENTS GRANTED BY THE UNITED STATES PATENT-OFFICE.

GRANTED SEPTEMBER 4TH, 1883.

284,177. Process of and Apparatus for Desulphurizing Ores. William Frank Browne, New York City.
284,178. Method of and Apparatus for Desulphurizing Ores. William Frank Browne, New York City
284,181. Furnace. Gottlieb F. Burkhardt, Boston, Mass.
284,233. Process of Dephosphorizing Iron in an Open-Hearth Furnace. Jacob Reese, Alleghany, Pa.
284,246. Bagasse-Furnace. John C. Semones, Minden, Neb.
284,287. Crucible, Muffle, etc. Thomas Egleston, New York City.
284,293. Amalgamating-Pan. Charles Gracey, Contention, Ariz.
284,383. Manufacture of Iron in Blast-Furnaces. Charles Cochrane, Stourbridge, County of Worcester, England.
284,384. Furnace for Reducing Ores. Victor Colliau, Detroit, Mich., Assignor to the Colliau Furnace Company, same place.
284,392 Amalgamator. Joseph C. Dane and William L. Card, La Crosse, Wis.
284,401. Ore-Separating Machine. Orison L. Farnham, St. Johnsbury, Vt., Assignor to John H. Paddock, same place.
284,458. Gas-Retort Furnace. George A. McIlhenny, Washington, D. C.
284,502. Plastic Refractory Material for Repairing Ingot-Molds. Thomas Smith, Alliance, O.
284,550. Process of Annealing Cast-Steel or Iron. James Henderson, Bellefonte, Pa.
284,551. Process of Purifying Solid Iron, producing therefrom Malleable Iron or Steel without Fusion. James Henderson, Bellefonte, Pa.
284,552. Basic Process of Manufacturing Iron and Steel. James Henderson, Bellefonte, Pa.
284,553. Basic Process of Manufacturing Iron and Steel. James Henderson, Bellefonte, Pa.
284,554. Basic Process of Manufacturing Iron and Steel. James Henderson, Bellefonte, Pa.
284,560. Coal-Mining Machine. Richard Johnson, Belleville, Ill.
284,574. Basic Process for the Manufacture of Homogeneous Ingot Iron and Steel. Jacob Reese, Pittsburg, Pa.

GRANTED SEPTEMBER 11TH.

284,589. Purification of Mineral Oils. Alexandre André, Fils, Paris, France.
284,611. Rock Pulverizer. Francis M. Case and Willis Case, Denver, Colo.
284,613. Machine for Separating Stones from Clay. Harvey Cockell, Chicago, Ill., Assignor to Richard S. Reynolds, same place.
284,652. Furnace and Hollow Grate-Bar. Otis B. Morse, Great Falls, N. H.
284,691. Dumping-Car. Matthew Van Wormer, Melrose, Mass.
284,693. Cupel Mold. Henry W. Walker, San Francisco, Cal.
284,700. Rolling-Mill. S. T. Williams, Troy, N. Y., Assignor of one half to Robert W. Hunt, same place.
284,799. Hand-Drill. D. Fletcher Barber, Newton, Assignor of one half to Albert M. Gardner, Boston, Mass.
284,830. Furnace-Protector. David R. Fraser, Chicago, Ill.
284,850. Boring-Machine. Theodore Hofstatter, Jr., New York City.
284,865. Miner's Lamp. Charles A. Lee, Arlington, Tex.
284,895. Apparatus Employed in Sinking Pits or Shafts. Ildephonse Quinet and Arthur Denis, Denain, France.
284,946. Combined Pulverizer and Grader. William Commeans, Lilly Chapel, O.
284,949. Brick Machine. Jonathan Creager, Cincinnati, O.
284,950. Metallic Coal-Oil Barrel. James W. Cuthbertson, Bothwell, Ontario, Can.
284,967. Drill-Rest. Henry C. Laubach, Philadelphia, Pa., Assignor to Edward L. Bartlett, Baltimore, Md.
284,992. Reverberatory Smelting-Furnace. Riley P. Wilson, Cleveland, O.

GRANTED SEPTEMBER 18TH.

285,040. Furnace-Grate. William Kearney, Belleville, N. J.
285,098. Concentrator. David H. Anderson, Butte City, Mont., Assignor of one half to William H. Young and Hezekiah Rondebash, both of same place.
285,110. Ore-Concentrator. William F. Carter and John M. Adams, San Francisco, Cal.
285,111. Dry Gold-Separator. Salathiel C. Chaney, Chico, Cal.
285,113. Continuous Rolling-Mill. George W. Corbett and John E. Cunningham, Chartiers Township, Alleghany County, Pa.
285,232. Ore-Concentrator. Alexander D. Clarke, New York City.
285,297. Air-Compressor. Charles Moore, Philadelphia, Pa.
285,307. Ore Washer. John G. Roberts, Idaho Springs, Colo.

GRANTED, SEPTEMBER 25TH.

285,387. Power-Hammer. John C. Butterfield, Chicago, Ill.
285,388. Stamp-Mill. John C. Butterfield, Chicago, Ill.
285,389. Atmospheric Hammer. John C. Butterfield, Chicago, Ill.
285,390. Atmospheric Hammer. John C. Butterfield, Chicago, Ill.
285,391. Mortar for Stamp-Mills. John C. Butterfield, Chicago, Ill.
285,431. Utilizing Phosphorus and Steel Scrap in the Basic Process. Jacob Reese, Pittsburg, Pa.
285,508. Amalgamating Ores and Sands containing Gold. Almarin B. Paul, San Francisco, Cal.
285,516. Rock-Drill. Alfred Shedlock, Brooklyn, N. Y.
285,522. Regenerative Furnace. William Swindell, Pittsburg, Pa.
285,523. Apparatus for Washing and Separating Gold and Silver from their Ores. William J. Tanner, London, County of Middlesex, England.
285,538. Ore-Crusher. Frank Wheeler and William W. Wheeler, Meriden, Conn.
285,565. Method of Excavating and Apparatus therefor. Frederick Brotherhood, Charleston, S. C.
285,615. Incrustation-Preventive. James B. Hannay, Glasgow, County of Lanark, Scotland.
285,627. Rotating Furnace. J. Burrows Hyde, New York City.
285,628. Apparatus for Boring Rocks under Water. Joseph T. Jones and Joseph H. Wild, Leeds, County of York, England.
285,629. Ratchet-Drill. Robert K. Jones, Liverpool, County of Lancaster, England.
285,638. Process of Producing Babbitt Metal. Amos C. Mann, St. Louis, Assignor of one fourth to Franz Krein, same place.
285,664. Conveyer. Frank I. Pearce, Chicago, Ill., Assignor to the Link Belt Machinery Company, same place.
285,718. Helve of Power-Hammers. Charles W. Willard, Chicago, Ill.
285,726. Drilling-Machine. William F. Barnes and John Barnes, Rockford, Ill.
285,733. Ratchet-Drill. Cemer Thomas Colebrook, Islington, County of Middlesex, England, Assignor to himself and Joshua Rose, New York City.
285,743. Air-Compressor. William T. Fox, Rochester, N. Y.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Oct. 19.

There is no change of interest to report in the mining market this week. Business is still confined to a few fancy stocks, and the transactions outside of these are very limited. Harlem was the most active stock in the market and was a little stronger. A few of the Tuscarora stocks exhibited a little strength, especially Navajo, which sold at very strong prices today. The general tone of the market was steady. A full summary is given below. The total number of shares sold aggregates 152,376, as against 193,710 last week.

The Comstock shares have been moderately dealt in at steady prices. California was quiet and steady, selling from 17@20@18c. Consolidated Virginia was strong, under a small business, selling from 45@56c. Sierra Nevada was also strong; it sold from $4@$4.30. Union Consolidated was quiet and steady at $3.90. Mexican was moderately dealt in at steady prices; it sold from $3.40@$3.75, assessment paid, and from $2.45@$2.25 assessment unpaid. Ophir was strong, with a small business; it sold from $5@$6.25. Hale & Norcross was fairly dealt in and was quite weak; it sold from $2.75@$1.10. Savage sold at $1.10. Yellow Jacket at $3.50, and Best & Belcher at $3. Sutro Tunnel was active and irregular, selling from 16@18@17c.

The Leadville stocks were very quiet at about steady prices. Amie was irregular, under a very active business, selling from 13@9@11c. Chrysolite was quiet and a little weak, selling from $1.20@$1.10. Dunkin was steady at 25@28c. Iron Silver was quiet and steady, selling from $3.15@$3. Leadville sold at 40c., under a small business. Little Chief was moderately dealt in at steady prices; it sold from 60@57c. Little Pittsburg was also steady, under a small business, selling from 62@65@64c. Climax sold from 9@8c.

The Bodie stocks were quiet and steady. Bodie Consolidated was quite strong, with a small business, selling from 59@70c. Standard was quiet and irregular, selling from $6.25@$5.63@$5.75. Consolidated Pacific sold at 45c., and North Standard at 16c.

The Tuscarora stocks were moderately dealt in at strong prices. Grand Prize sold at 47c. Belle Isle was quiet and weak, declining from 50@41c. Navajo was very strong, under a moderate business; it sold from $3.60@$4.60. North Belle Isle was also strong, with a small business, selling from 50@64c. Elko Consolidated was very active at irregular prices; it sold from 2@4c.

In the miscellaneous list, Alice was quiet and steady, selling from $2.65@$2.75. Eureka Consolidated was moderately dealt in at irregular prices; it sold from $5.63@$6.25@$5.50. Horn-Silver was fairly dealt in at steady prices, selling from $6.63@$7. Robinson Consolidated was very irregular under a moderate business; it sold from 36@45@40c. Sierra Grande was quiet and steady at $1.05.

Barcelona was moderately active at irregular prices, selling from 25@30c. Decatur was quiet and steady, selling from 4@3c. Eastern Oregon was fairly active at irregular prices; it sold from 48@41@42c. Harlem continues to be very actively dealt in, and has been quite strong; it sold from 86@93c. Silver Cliff sold from 10@8c. under a small business. Sonora Consolidated was very active at steady prices; it sold from 22@25@24c.

The Homestake Company has reduced its monthly dividends from $50,000 to $25,000.

The Ontario Mining Company, which is at the head of the list as a dividend-paying property, has resumed the payment of dividends, and the one just declared makes a total of $5,000,000 paid to its stockholders since the mine was placed on a dividend-paying basis.

A dividend of twenty cents a share has been declared by the Father de Smet Mining Company. This is the first since last July.

MEETINGS.

The Carbonate Hill Mining Company, No. 115 Broadway, New York City. Annual meeting of stockholders and election of trustees, November 8th, at one o'clock P.M.

The Empire Copper Company, office of M. H. Hoffmann, Room 7, No. 629 Walnut street, Philadelphia. A special meeting of stockholders, for the purpose of authorizing a sale of the pine timber on a part of the company's lands in Keweenaw County, Michigan, November 10th, at one o'clock P.M.

The Resolute Mining Company, office of M. H. Hoffmann, Room 7, No. 629 Walnut street, Philadelphia. Special meeting of stockholders for the purpose of authorizing a sale of a part of the company's lands in Keweenaw County, Michigan, November 10th, at twelve o'clock M.

The Spring Creek & Rockerville Water and Mining Company, office of T. J. Temple, No. 155 Broadway, New York City. Annual meeting of stockholders, November 14th, at three o'clock P.M.

DIVIDENDS.

The Crescent Mining Company, of Utah, has declared dividend No. 4, of $30,000, payable at Salt Lake City, October 31st. The total dividends to date are $150,000.

The Father de Smet Mining Company, of Dakota, has declared a dividend of twenty cents per share, payable October 31st, at the office of Laidlaw & Co., No. 14 Wall street.

The Homestake Gold Mining Company, of Dakota, announces its regular dividend of $25,000 for September, making a total thus far of $2,237,500. The present dividend is payable at the office of Lounsbery & Haggin, transfer-agents, Mills Building, No. 15 Broad street, on October 25th.

The Ontario Silver Mining Company, of Utah, has resumed its regular dividends, and the eighty-eighth, amounting to $75,000, will be paid by Messrs. Lounsbery & Haggin, transfer-agents, at their office, Mills Building, No. 15 Broad street, on October 31st. The above dividend makes a round total of $5,000,000 paid to date.

PIPE LINE CERTIFICATES.

Watson & Gibson, petroleum brokers, No. 40 Broadway, report that the petroleum market during the past week has been dull and featureless.

The flurry in Wall street and decline in prices of meats and breadstuffs in Chicago would naturally have exercised a depressing influence on the petroleum market. That oil has held so steady and firm is evidence that the leading bulls are supporting the market. The news during the week has encouraged the bulls, as Howe No. 11 and Balltown No. 14, were of no value as producers, and reports were circulated that Bradford and Allegheny fields were declining in production. The "runs," so far this month, are about 10,000 barrels daily less than the shipments, and charters continue large. The petroleum market is so stagnant that the public are not inclined to load up, and until the temper of general speculation changes, we do not anticipate any bull movement of importance.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Oct. 13	$1.10¾	$1.11⅞	$1.10	$1.10¼	4,748,000
15	1.10⅝	1.11⅛	1.10½	1.11	3,380,000
16	1.11⅜	1.1 ⅞	1.10⅛	1.10⅛	4,175,000
17	1.10¼	1.10¾	1.09⅝	1.10	4,023,000
18	1.09⅝	1.11	1.09⅝	1.10⅝	2,577,000
19	1.10⅝	1.11¼	1.09¾	1.09⅞	2,816,000
Total sales					21,719,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, October 18.

There is but little to be said regarding the market for mining stocks the past week. There is but very little doing, either in coppers or silvers, and prices have had a downward tendency. Calumet & Hecla is now selling at $239½, ex dividend $5 per share, which is a decline of $½. Quincy declined from $51 to $50 on small sales. Pewabic declined from $1½ to $1¼, with late sales at $1⅜. An assessment of $1 per share has been levied upon this stock, payable on the 23d inst. Osceola sold same as last week at $19. Franklin sold at $12⅞ for a small lot. The rest of the copper list is totally neglected. The whole amount of sales for the week is less than 600 shares, and fully reflects the entire want of activity in the market.

The silver stocks are without any special feature. Catalpa declined from 32½c. to 30c. Sullivan steady at 87½c. Silver Islet sold at $3. San Pedro sold at 15c.

At the Mining Stock Exchange, business continues to rule dull, and, with the exception of Empire prices are lower. Empire is in fair demand, and but little stock offering. Sales were made yesterday at 24@25c.; to-day, 26c. is bid without bringing out any stock. Bowman Silver is dull and no disposition to trade in it; price rules at 12@13c. Massachusetts & New Mexico has almost faded out of sight; occasional sales at 3@4c. In Sullivan, there is more doing than at the old Board, and better prices are obtained. Sales at 87½@92½c. regular, and 97½, buyer 60 days.

3 P.M.—At the afternoon Boards, Empire sold at 28c.; closing 27c. bid. Sullivan steady at 92½@90c., seller 30. Franklin sold at $12. Quincy offered at 50c. Remainder of market unchanged.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended October 19th, as compiled from various sources, amounted to $218,000, as against $296,000, reported for the previous week. The receipts from January 1st, 1883, to date are $9,163,047.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended October 13th	$272,158
Corresponding week last year	25,700
Since January 1st, 1883	11,550,234
Corresponding period last year	44,327,495

Imports.

Week ended October 13th	$7,022
Corresponding week last year	434,827
Since January 1st, 1883	12,913,242
Corresponding period last year	3,803,812

Foreign Bank Statements.—The governors of the Bank of England, at their weekly meeting, made no change in the bank's minimum rate for discount, and it remains at three per cent. During the week, the bank lost £311,000 bullion, and the proportion of its reserve to its liabilities was raised from 42¼ to 43¾ per cent, against 35 11-16 per cent at this date a year ago. October 18th, the bank lost £30,000 bullion on balance. The weekly statement of the Bank of France shows losses of 350,000 francs gold and 360,000 francs silver. The statement of

Digitized by Google

the Imperial Bank of Germany shows a loss of specie amounting to 2,260,000 marks.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 or ounce troy; gold at the standard $20.67 per ounce roy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

MINES.	States.	Month of September.	Year from Jan. 1st, 1883.

METALS.

NEW YORK, Friday Evening, Oct. 19.

Copper.—The lake companies have made an arrangement with the leading companies to extend the contracts about to expire to the end of the year, the price to remain the same, 15c.; and the quantity involved being, it is stated, eight millions of pounds. In other kinds, little has been done, Baltimore selling in a small way at 14⅝c. We quote for Lake 15⅛@15¼c.; and for other kinds, 14¼@14¾c., according to brand. England has again receded, being cabled to-day £60 15s. for Chili Bars. It appears to be becoming a question who will survive in a struggle in the markets of the world, our silver-bearing copper material and high-grade copper from oxidized ores, or the crude copper of Chili. The balance is strongly in our favor, but the time before Chili producers fall off may be a long one.

The trade will learn with sorrow of the sudden death, yesterday afternoon, of Mr. Nathaniel S. Simpkins, Jr., who has been identified with the Calumet & Hecla Company since its inception. His brother, Mr. John Simpkins, was president of the Huron Company when the agent of that company, in building a road, uncovered the Calumet & Hecla conglomerate. The two brothers, with Captain Frue, became interested in the property. They engaged Captain Hardy, of the Quincy, to open out the mine, his successor being Professor Agassiz, who had acted as manager of the Boston & Albany. On the death of his elder brother, who managed the affairs of the company in the East, N. S. Simpkins, Jr., in 1870 took charge, and for many years practically controlled the copper market.

Messrs. James & Shakspeare, of London, have issued the following statistics of copper in England and France, including metal afloat:

	Sept. 1 to 30. Imports. Tons.	Deliveries. Tons.	
Fine foreign, chiefly Australian.	802	$80	London.
Chili Bars	2,629	808	Liverpool and Swansea.
Chili Ingots	340	255	
Chili In ores and regulus	307	5	
American	729	770	
Spanish precipitate and sundries.	4,026	4,145	
Totals, England	8,833	6,963	
American	525	575	France.
Chili bars, ingots, and Barilla	1,535	1,080	
Sundries	95	95	
Total, England and France	10,988	9,293	

	Stocks. Sept. 29. Tons.	Aug. 31. Tons.	
Fine foreign, chiefly Australian	3,900	4,078	London.
Chili Bars	25,155	23,334	Liverpool and Swansea.
Chili Ingots	536	451	
Chili In ores and regulus	2,115	1,813	
American	97	138	
Spanish precipitates and sundries	4,338	4,457	
Totals, England	36,141	34,271	
American	340	390	France.
Chili bars, ingots, and Barilla.	1,922	2,047	
Sundries	30	30	
Total, England and France	38,433	36,738	
Advised by mail and telegram:			
Chili	10,200	11,209	
Australian	900	900	
Stock and afloat, gross totals	49,533	48,845	

	Jan. 1 to Sept. 30. 1883. Tons.	1882. Tons.	1881. Tons.
Imports	71,409	58,458	57,709
Deliveries	68,103	62,606	61,403

The last figures are significant. They show an enormous increase in the imports thus far.

Tin.—The market is quiet, with an undercurrent of weakness. For Spot Straits 20⅝c. is asked. We note a sale of 200 tons, delivery after January, at 20⅝c. London cables £93 7s. 6d.@£93 10s.

Lead.—Under sales in small parcels aggregating 500 tons of Common and Refined, the market has receded from 4·20 to 4⅛c., with Refined at 4·15c. More is offered at these figures, but there are no buyers, the latter maintaining an attitude of reserve. The short season will soon be over, and a falling off in the demand from that quarter is looked forward to. Should the winter prove an open one, the pipe trade will continue brisk; if not, there will be a contraction of the supplies needed for that purpose. It is reported that desilverizers are making very favorable terms with smelters, the offerings of base bullion being very large.

Messrs. John Wahl & Co., St. Louis, wire us as follows to-day:

Sales during the week aggregate 250 tons of Refined at 3·90c., delivered at buyers' works; 400 tons November delivery, at the same figure; and 300 tons of ordinary Missouri to Eastern consumers at 3·80c. Our market closes firm at 3·90 for spot Refined, on account of the railroad switchmen's strike here.

Messrs. Everett & Post, of Chicago, telegraph to-day:

In our market, sales of Refined and Common have been more freely made since our last, and several hundred tons have been placed at 3·90c., 3·92½, and 3·95c. Our market is now heavier, flat, and weak, buyers, as they expect a decline, holding off, and making their purchases only for immediate delivery.

Spelter.—This metal has relapsed into dullness, and is weaker, ordinary Western being procurable under 4½c. European advices are higher.

Sheet-Zinc is very low, selling here for 5⅝@5¾c. in jobbing lots, in spite of the fact that the card rate in the West is 6c., less 11 per cent for cash.

Antimony.—Antimony is a little firmer, at 10½c. for Cookson's, and 9c. for Hallett's.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Oct. 19.

American Pig.—The event of the week has been a further reduction by the Thomas Iron Company of its prices of foundry iron, to $20.50 for No. 1 and $19.50 for No. 2, at which figures sales of about 1000 tons were made in the beginning of the week, with no further business during the past two days. We quote $20.50@$21.50 for No. 1 and $19@$20 for No. 2, with mill irons, which are a little more active, at $17.50@$19 at tide. Bessemer pig is dull, foreign being freely offered at $20.50 at tide. Spiegeleisen is quiet at $30@$30.50.

At the Exchange, the following sales were recorded:

Monday, 200 tons American Pig, No. 1, January, $20. Wednesday, 500 tons American Pig, No. 1, Janary, $20; 300 tons No. 1, February, $20¼.

Scotch Pig.—The market continues dull and lifeless, though there is no exceptional cutting. Arrivals are light, aggregating 1200 tons.

We quote ex ship and to arrive: Coltness, $23.25; Langloan, $23.25; Summerlee, $22.50@$23; Eglinton, $21; Glengarnock, $22@$22.50; Dalmellington, $21.

At the Exchange, the following lower cable quotations were received to-day: Coltness, 57s.; Langloan, 56s. 9d.; Summerlee, 55s. 6d.; Gartsherrie, 54s. 3d.; Glengarnock, at Ardrossan, 53s. 3d.; and Eglinton, at Ardrossan, 47s. 6d. Warrants at the Exchange to-day were 51s. 7d.

Rails.—A part of the contracts alluded to last week were 16,000 tons Edgar Thomson and Homestead, at $36.50, delivered at Pittsburg. It is stated that since then a lot of 4000 tons has sold at $34.25 at mill, though the report is discredited. We quote $36.50@$37 at mill.

Old Rails.—There is very little doing, the demand being slack. Sales of Ts have been made as low as $21. We quote $21@$22.

Scrap is dull at $22.50@$23 ex ship.

Philadelphia. October 19.

Erroneous and unjustifiable reports have been circulated concerning the condition of the Pennsylvania iron trade. Very few furnaces have gone out of blast recently, although it is true that several companies contemplate blowing out shortly, partly on account of low prices, and partly in order to make repairs when the market is dull and stocks large. Foundry irons continue dull and weak, and the efforts made to move them at concessions have not resulted in sales of more than ordinary lots. The production of foundry iron will probably fall off, as stocks are large, and buyers are not disposed to cover requirements for the future. Prices range from $19@$22. A number of transactions have taken place at $21 for No. 1 and $19.50 for No. 2; some No. 1 has sold at $21.50 and a little at $22. The tone of the forge iron market is somewhat better, and the stronger companies decline to follow the downward tendency, confident that the market will take care of itself.

Foreign Iron.—Bessemer is offered at $20.50, but bids have been withdrawn, and buyers are not urgent just now. Spiegeleisen is in more active request at $30@$31. A few hundred tons of Scotch iron have been ordered.

Muck Bars.—A few hundred tons have been sold at $33.50@$34. Demand is active.

Blooms.—Quotations are given at $58 for Charcoal, and $47@$48.50 for Anthracite.

Merchant Iron.—Card rates have been changed from 2·30@2·20c., but very little iron sells above 2·10c.; 2c. is all that can be had for most of the iron moving. Some country mills have sold Refined iron under 2c., and the tendency is downward. It is announced that two or three mills will come to single turn next week. Western iron has been shipped into Eastern Pennsylvania, and interferes with trade.

Nails.—Trade price, $2.90; jobbing price, $3; in-

side special rates, $2.85. Several car-load lots have been ordered this week, in view of the probability of great activity in building construction throughout the winter.

Plate and Tank Iron.—No large orders have been booked, but several are in sight, and some specifications have arrived which will result in large business within a week. Boat plate is 2·35c.; Tank, 2·40@2·50c. Shell and Flange are without change.

Structural Shapes.—A few more inquiries for fair-sized lots have arrived, and orders will be placed this week. Quotations are 2·40c. for Angles and 3·50c. for Beams and Channels. Some concessions have been solicited and will be extended when large orders are to be had.

Sheet-Iron.—A large amount of sheet-iron has been ordered this week, and inquiries for thin sheets continue active. Card rates unchanged.

Steel.—Merchant steel is in quite active request, especially for the better makes. Competition is active on the low grades.

Steel Rails.—A fair amount of business was transacted in ordinary lots for delivery in November and December, and it is probable that in a few days some heavy business will be placed for winter delivery. Quotations are $37 $38.

Old Rails.—Quotations are nominally $23.50 for Tees, $24.50 for Bridge rails, and $26 for Double Heads.

Scrap.—Quotations, $20@$25, according to quality. Cargo, nominal, at $23.

Pittsburg. October 18.

To-day's probabilities point to an improving demand for pig-iron, because of the gradual diminution of stocks in local furnaces. Nine furnaces are now in blast, and three out. Lucy furnace No. 2 was blown out last Monday, and will be relined and started on January 1st. Isabella furnace No. 2 has been out for a year. The average production of the home furnaces is about 1600 tons a day. Makers of outside iron are in town, offering iron for future delivery at low prices. Several mills are working single turn, and it is said to-day that two or three others will follow suit. A number of buyers are ready to anticipate requirements as soon as assured that lowest prices have been reached. Very little iron is to be found in mill-yards. Sales of Foundry have been made in 50 to 100-ton lots at $20@$21 for No. 1, and $18@$20 for No. 2, on time. Bessemer, $21@$21.50. Forge, $17.50@$18 in 100 to 500-ton lots. Muck Bars are selling at $33 cash. Manufactured iron is still weak and dull at 1·80@1·90c. The consuming interests are prepared to place large orders to run them until the last of the year, as soon as the supply and demand are more nearly equalized. A week or two will probably develop new features and lead to an improvement. Several lots of iron have been shipped East. Nails are quoted at $2.80@$2.90, and are selling in large lots at $2.70. Large lots of pipes have been sold at 75 per cent off list. Between 10,000 and 15,000 tons of steel rails have been contracted for at $36.50@$37. Sheet-iron is in fair request, and galvanized is moving freely. The steel-mills are working as usual, but manufacturers complain of low prices. Old Rails are quoted at $24.25@$24.50. Spikes, 2·60c. Splice Bars, 1·90c. Track Bolts, $3@$3.25. Crop-Ends, $23.50 for American. Scrap, $20@$22. Car-Axles, $31.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Oct. 19.

Anthracite.

The condition of the anthracite coal market is unchanged, no movement whatever, so far as we can learn, having been made to bring about a better condition of affairs. Prices are low, and sales light, so that the excess of coal over that required to fill engagements previously made must be piled up somewhere. The Eastern trade is exceptionally dull, while the river trade, as is usual at this time of the year, is active, the stocking up of the many towns along the Hudson going on now. Some of the dealers of that section are now pretty well supplied, however, and the first ice will divert to this market large quantities of coal. The policy appears now to utilize the time before the closing of navigation, but it may well be questioned whether a considerable quantity of coal will not have to be stored at various points to relieve an excess. The trade of course is disappointed that no effort has been made to protect its interests, and it urged with some force that it is unjust to load dealers up with coal earlier in the season and then allow the price to drop off as it has.

John H. Jones, official accountant, has issued the following statement of anthracite coal tonnage for the month of September, 1883. This statement includes the entire production of anthracite coal, excepting that consumed by employés, and for steam and heating purposes about the mines:

	Sept., 1883.	For year 1883.	For year 1882.	Difference.
Phila. & Reading RR.	1,171,187	7,160,876	4,899,125	I. 2,261,751
Central RR. of N. J.	*.....	1,745,399	3,068,630	D. 1,323,231
Lehigh Valley RR.	†606,140	4,568,221	4,237,307	I. 330,914
Del., Lack. & W. RR.	472,933	3,675,135	3,343,633	I. 331,502
Del. & Hud. Canal Co.	‡359,160	2,530,865	2,240,983	I. 289,882
Penna. RR.	273,775	1,999,887	1,747,105	I. 242,781
Pa. Coal Co.	154,129	1,096,595	1,045,970	I. 50,624
N. Y., L. E. & W. RR	47,030	268,542	195,494	I. 73,048
Total	3,084,355	23,035,520	20,778,247	I. 2,257,273

* Included in tonnage of the Philadelphia & Reading Railroad.

† This amount includes the production of the mines of the State Line & Sullivan Railroad Company, amounting to 7761 tons.

‡ In addition, there were 67,728 tons transported from the mines by the Delaware & Hudson Canal Company, during September, which is included in tonnage of other interests.

The stock of coal on hand at tide-water shipping points, September 29th, 1883, was 538,490 tons; on August 31st, 1883, 576,132 tons; decrease, 37,642 tons.

Bituminous.

The scarcity of cars is the complaint from a number of quarters, but current business is so slack that it has no effect whatever on values.

Horsford's Acid Phosphate

For Overworked Professional Men.

Dr. Charles T. Mitchell, Canandaigua, N. Y., says: "I think it a grand restorer of brain force or nervous energy."

DIVIDENDS.

SAN FRANCISCO, Oct. 16, 1883.

THE FATHER DE SMET CONSOLIDATED GOLD MINING COMPANY has declared

DIVIDEND NO. 29,

of twenty cents per share, payable at the office of Laidlaw & Co., 14 Wall Street, New York, on the 31st inst.

Transfer-books will close on the 23d inst.

H. DEAS, Secretary.

HOMESTAKE MINING COMPANY, MILLS Building, 15 Broad Street,

NEW YORK, Oct. 15, 1883.

DIVIDEND NO. 62.

The regular monthly dividend of TWENTY (20) CENTS per share has been declared for September, payable at office of Transfer-Agents, Lounsbery & Haggin, Mills Building, 15 Broad Street, on 25th inst. Transfer-books close on 20th inst.

LOUNSBERY & HAGGIN, Transfer-Agents.

ONTARIO SILVER MINING COMPANY, Mills Building, 15 Broad Street,

NEW YORK, Oct. 15, 1883.

DIVIDEND NO. 88.

The regular monthly dividend of FIFTY CENTS per share has been declared for September, payable at office of Transfer-Agents, Lounsbery & Haggin, Mills Building, 15 Broad Street, on 31st inst. Transfer-books close on 25th inst.

LOUNSBERY & HAGGIN, Transfer-Agents.

ROTHWELL'S

Great Map of the Wyoming Valley.

This, the most elaborate and accurate topographical map ever made in this country, outside of the Coast Survey, covers an area of TWO HUNDRED SQUARE MILES, and the work upon it cost over $12,000. It represents a coal-field which produced in 1882 over 13,000,000 tons of Anthracite. The Map was constructed altogether from original surveys. Every Road, Colliery, Building, or land or property line existing at the time is accurately located. The surface configuration is shown by CONTOUR LINES TEN FEET APART, VERTICALLY; and the elevation of every point above sea-level is given

But a small edition of this Map was printed, and the plates were then destroyed.

A few copies are for sale

Price: On thick heavy paper $25

On bond paper, for mounting 25

The six sheets can be mounted separately, or in a single roll 15 feet long by 42 inches wide.

MAPS.

ARIZONA AND NEW MEXICO.—This map shows all the Township Surveys, Private Land Claims, Post-Offices, and Settlements. It also exhibits the Explorations of other Government and Private Expeditions, including the facts developed by the Surveys for the Routes of Projected Railroads, etc., 1881. Scale, one inch to thirty-three miles. Colored, 24×17 inches. Pocket form, $1.

COLORADO.—Topographical and Township Map of Part of the State, exhibiting the San Juan, Gunnison, and California Mining Regions. By Louis Nell. Substantially same as above. Post-offices, March 1st 1880. Scale, 1 inch: 9 miles, 1-570,240. Plain sheets for wall, 90 cents.

COLORADO.—Cannon's Map of the Mineral Belt of Colorado. Taken from the Records of the Surveyor-General's Office, and other reliable Official Sources. Showing, in colors, the Mineral Belt, Gold Districts, Silver Districts, Coal Districts, County Lines, and Boundaries of Land Districts. There are also given the Capital, County Seats, Township Lines, Railroads, and Projected Railroads. Scale, 1 inch: 10 miles. Size, 26×30 inches. Pocket form, $1.50: as a wall-map, $2.

SAN JUAN MINING REGION (COLO.).—Kibbe's Geographical and Geological Map of the San Juan Mining Region. 1881. Shows county lines, wagon-roads, stage routes, trails, railroads, cities and towns with post-offices, camps with post-offices, reduction-works, mountain peaks, continental divide Also (by colors), eruptive rocks, Carboniferous, Cretaceous, Jura Trias. Elevations above sea-level. Scale, one half inch to the mile. 22×27 inches. Includes, on same sheet, a reduced Map of the State of Colorado. Printed in colors, with board covers. $1.50.

COLORADO.—Topographical and Township Map of the State. Compiled from U. S Government Surveys and other authentic sources, by Louis Nell, Civil Engineer. By means of symbols, the following mass of facts is graphically shown: Railroads in operation; Railroads chartered or in progress: Wagon-roads; Wagon-roads proposed; Trails; Drainage dry during the greater part of the season; County-seats: Post-offices; Villages; Townships subdivided; Townships surveyed in outlines; Contour-lines, with vertical intervals of 1000 feet; Altitudes in feet above sea-level, by barometer observations and by spirit-levels; Private grants; Military reservations; Indian reservations ceded to the U. S. Government; Arable land, with irrigation. Tables of Areas of Counties; Astronomical Positions; Arable Land. Scale, 1 inch: 10·5 miles. Size, 31X40 inches. Pocket form. $1.50 on thick paper.

IDAHO.—The Wood River Region of Central Idaho, giving the first correct Geography of that recently explored and remarkable Belt of Discoveries of Gold and Silver Mines on the tributary streams of the WOOD and LITTLE WOOD Rivers, on the Upper Waters of the SALMON RIVER, among the SAWTOOTH MOUNTAINS, and on the Forks of the BOISE RIVER; embracing the Mount Estes and Custer Mines on the north and the Oregon Short Line Railroad on the south. Prepared by Frank J. Scott. Scale, 5 miles to the inch. Size, 15 x 26 inches. In paper pocket. Price, $1.

MEXICO.—Map of Mexico. Showing Railroads, Broad Gauge and Narrow-Gauge, Constructed; and Railroads, Broad-Gauge and Narrow-Gauge, Proposed. This very large and finely-engraved Map, constructed originally by the government for official purposes, contains all the information obtainable by it, and shows minutely the towns and villages of the entire country. Scale: 26·6 Mexican Leagues to the degree, and 69·16 English Miles to the degree; also, Kilometrical Scale. 1881. Size, 53X41 inches. Printed in colors. Pocket form, $5.

MAP OF MINING CLAIMS ADJOINING LEADVILLE, California Mining District, Lake County, Colo. By Edward Rollandet. 1879. Mounted on muslin, $2.50. In cloth-bound covers, $2.

MINING MAP OF UTAH.—Showing the location of the Mining Districts, over an extent of territory 150 miles from North to South. Compiled from U. S. Government Surveys and other authentic sources. Scale, one inch to four miles. Colored. 1879. Pocket form. $1.50.

NEW SECTIONAL AND MINERAL MAP OF UTAH.—Pocket form. Compiled from the latest U. S. Government Surveys and other authentic sources, exhibiting the Sections, Fractional Sections, Counties, Cities, Towns, Settlements, MINING DISTRICTS, Railroads, and other internal improvements. Scale, one inch to eight miles. Colored, 1878. $3.50.

POCKET MINING ATLAS OF THE MINES OF THE UNITED STATES.—Showing the Mines of NEVADA: the Comstock Lode, the Eureka, Treasure Hill, and Tuscarora Districts; CALIFORNIA, including Map of the Bodie District; COLORADO, including the Leadville, Silver Cliff, San Juan, Caribou, and Central City Districts; DAKOTA, including Map of Deadwood; MONTANA, IDAHO, UTAH, ARIZONA, NEW MEXICO, LAKE SUPERIOR REGION, the SOUTHERN STATES. 1880. Printed in colors, and bound in flexible leather covers. Price, $1.

SAN JUAN MINING REGION (COLO.).—Stockder's Map of San Juan Mining Region, compiled from U. S. Surveys and other Authentic Sources. 1881. Shows county boundaries, district boundaries, wagon-roads, trails over mountain passes from river basin to river basin, continental divide, timber-line (11,000 to 11,500 feet above sea-level), etc. Scale, 1 inch to the mile, or 1 = 63,360. 28 × 38 inches. Pocket form, stiff paper cover. $1.50; or as a wall map, $1.50.

VENEZUELA threatens to become one of the more formidable of the competitors of our Western copper mines in the markets of the world, to judge from the reports of the leading concern, the Quebrada Railroad Land and Copper Company, a fusion of the Bolivar Railroad Company and the New Quebrada Copper Company, in which together £1,000,000 have been invested. In the first six months of the present year, the company shipped to the coast 15,300 tons of ore, 2150 tons of regulus, and 470 tons of "kernels." With a considerably smaller output, the mines had dividends last year amounting to £13,000.

THE programme for the annual meeting of the American Society of Mechanical Engineers in this city next week has been issued. There will be an opening session and supper on Wednesday evening, October 31st, followed by two meetings, in the morning and afternoon of Thursday. On Friday, the society has accepted the invitation of Mr. HENRY R. TOWNE, of the Yale & Towne Manufacturing Company, to visit its extensive establishment at Stamford, Conn. In the evening, the last session will be held, like the others, in the rooms of the American Society of Civil Engineers. For Saturday, the New York, West Shore & Buffalo Railroad has tendered an excursion over its line to Kingston and return. A number of papers are already promised, and vigorous efforts are making to have the meeting a worthy successor of the Cleveland gathering.

A NUMBER of gentlemen prominently connected with mining in Utah, among them R. C. CHAMBERS, O. J. HOLLISTER, W. S. GODBE, J. K. WALKER, J. E. CLAYTON, E. P. FERRY, and E. AUSTIN, have formed an organization called the Salt Lake Mining Institute. Its principal object is praiseworthy, as it is proposed to establish a museum of ores of minerals, and to collect, classify, and preserve all information obtainable respecting the mineral resources of Utah, and other States and territories in a less degree. It is proposed to gather a library, collect copies of reports, plans, specifications, and drawings of machinery, and to publish, at regular intervals, reports on the condition, progress, and output of the mines. The plan is an excellent one, and we are pleased to hear that a building has already been secured for the purpose. With the active co-operation of those interested in mining in the territory, its present officers, Mr. JAMES E. CLAYTON, President ; Mr. O. J. HOLLISTER, Secretary ; and Mr. E. AUSTIN, Treasurer, will be able to make it a model institution, whose success we hope will soon be such as to lead other prominent districts to follow its example. We shall all look forward to its early career with interest, and sincerely wish that it may prove one of lasting utility.

THE battle of the stoves has been and is still raging fiercely in England. The first gun was fired by Mr. EDWARD A. COWPER, of London, the inventor of the Cowper stoves. At the meeting of the Iron and Steel Institute, at Middlesborough, last month, in a somewhat self-congratulatory paper, Mr. COWPER deliberately claimed that his stoves save about 20 per cent of fuel per ton of iron, and increase the make of iron about 20 per cent, and that on coke an average of 100 stoves showed a saving of a little over 5 cwts. of coke per ton of iron, and on raw coal 7½ cwts. He estimated that the stoves pay for themselves generally in a year, and as £460,000 had been expended on the 360 stoves built in different parts of the world, he took unto himself the credit of saving the iron-masters that sum annually. In these extravagant claims, however, Mr. COWPER stood alone, and even one of his urgent supporters, Mr. CHARLES COCHRANE, did not appear to be willing to go so far. At his works, furnaces with a capacity of 7000 cubic feet used in 1855 39·46 cwts. of coke, while in 1882 the largest furnaces, with 34,000 cubic feet capacity, were making iron with 19·38 cwts. Mr. COCHRANE was willing to concede one half of the saving to the higher temperatures of blast, and the other half to the increase in the size of the furnaces. Mr. CHARLES WOOD, another iron-master, stated that he had put Cowper stoves in place of cast-iron stoves, and had found that the fuel consumption fell off from 24 cwts. to 20·75 cwts. ; but the former figure was challenged by Mr. WILLIAM WHITWELL, because it was not a reasonable consumption for a good working furnace. He objected, also, to the testimony of Mr. COCHRANE, when he claimed that one half the reduction in the quantity of fuel used now, as compared with the consumption thirty years ago, was due to the use of brick stoves. His own firm had, with cast-iron stoves, in ten years carried down the fuel consumption from 32 to 24 cwts. of coke per ton of iron. He gave an instance, also, where in this country the enlarging of a bell by eighteen inches had made a furnace a paying investment which had until then been a losing concern. This, and a number of remarks made during the course of the debate, proved that it has been too often the tendency to credit the brick stoves with results that are probably due in part, at least, to many modifications in design of plant and method of working ; and it was repeatedly implied or directly urged by several speakers that, in the heat of the controversy of cast-iron *versus* brick, and COWPER *versus* WHITWELL *versus* MASICKS, and CROOKS *versus* FORD and MERCUR and other designers of brick stoves, other important issues had been neglected. Mr. RICHARD HOWSON in his paper on Blast-Furnace Economy in Relation to Design, discussed at the same time, dwelt particularly on this point. He also avowed himself in some degree a champion of the much-abused pipe-stove, which found a number of vigorous defenders. We believe that in this country there are many furnace-men who are not quite prepared to allow themselves to be carried away by the tide of popular favor in behalf of the brick stoves. It has been apparently nobody's business to break a lance in their behalf, and the evidence in favor of their younger rivals is skillfully marshaled at all times and in all places.

At this meeting, the supporters of the iron stoves came out forcibly. Mr. EDWARD WILLIAMS, of Middlesborough, stated that, with five furnaces, the consumption of fuel, spreading over a long period, was practically 22¼ cwts., and while he would not replace his cast-iron stoves by modern brick stoves for any saving there would be in the operation, he would, in building new works, put in the latter. Mr. T. HUGH BELL did not even feel inclined to go so far, as he thought it would take them weeks of anxious debate, were they to build the Clarence works over again, before they decided in favor of either one or the other. Mr.

Digitized by Google

GJERS, an eminent iron-master, quoted his experience with four blast-furnaces built in 1870, for which he had put up twenty-four cast-iron stoves of his own design, at a cost of about one half per furnace more than that of a plant of brick hot-blast stoves. The average of fuel consumption for the first two years was 19·8 cwts.; for the first six years, 20·71 cwts.; and for twelve years, 21·63 cwts.

Taking the evidence submitted, and making due allowance for many other improvements, it may well be questioned whether the decrease of fuel consumption claimed by the advocates of the brick stove is as strong in its favor as they would make the metallurgical world believe, and in many instances it is undoubtedly a close question whether the mere substitution of one for the other form at an old furnace will in itself warrant the increased cost. As Mr. E. WINDSOR RICHARDS pointed out during the course of the debate, the fire-brick stoves are not all perfection. With dry, clean gas they give no trouble; but when ore is used like the Bilbao, carrying 12 and even 15 per cent of moisture, or in spiegel furnaces, the dust deposits are liable to become very troublesome. It is undoubtedly true that, to meet this trouble, their construction has been much improved, and we would note that at St. Nazaire, France, and in Germany, the additional safeguard of putting in dust-chambers is resorted to. Still, the fact remains that the iron stoves are not by any means as bad as some people would make them, and we trust that American iron-masters who have evidence on this point will come forward to their support.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

Saving Flour Gold.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: I am anxious to get the opinion of some of your correspondents as to the best methods of saving flour gold after passing over plates from the battery. It frequently happens here that professional advice is not available, and in many cases worthless when obtained. M. H.

ALMA, PARK CO., COLO., Oct. 19.

A Market for Serpentine Rock.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Will you be kind enough to state whether or not there is a market for serpentine rock? I have large quantities of it, and would like to utilize it. S. G. M.

MERIWETHER, S. C.

[Serpentine was formerly extensively used for baths, urinals, etc., and the finer grades for vases, paper-weights, and a large number of similar objects for household purposes. It has, however, of late years given way to other raw material, and, so far as we can learn, its market has contracted rather than expanded. In some instances, it has been used as a blast-furnace lining and as a refractory material in stoves, ranges, and metallurgical furnaces. Its value of course depends entirely upon its color, texture, size of good blocks, etc. It might be worth while for our correspondent to prospect his territory for chrome ore, as that frequently accompanies deposits of serpentine rock.—ED. E. AND M. J.

The Combustion of Fuel.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: In your issue of the 13th inst., page 230, you state that the German commission on the losses in the combustion of fuel argue that due deduction should be made for the fact that, in the ordinary combustion of fuel, the products of the combustion of the hydrogen are steam, and not water, and that they therefore reduce the calorific power of hydrogen to 28,800 instead of 34,220. It might be inferred from this that they had made a new discovery, or at any rate, that they were calling attention to a fact generally overlooked.

The truth is, that it is perfectly well known that the calorific power 34,220 of hydrogen refers to the heat developed when the steam produced is condensed, and that, if it is not condensed, allowance must be made for the latent heat of evaporation which would have been given out if it had been condensed, and also for the difference between the specific heats of steam and of water, in order to arrive at the useful or available calorific power of hydrogen.

This is elaborately and clearly set forth by Gruner in his *Traité de Metallurgie*, 1875, page 57, and in Percy's *Fuel*, 1875, page 170. Indeed, I had supposed it to be one of the fundamental facts perfectly familiar to every one who had occupied himself at all with heat calculations.

BOSTON, Oct. 19. Yours truly, HENRY M. HOWE.

PROF. J. LAWRENCE SMITH died recently at Louisville, Ky. He was a native of Charleston, S. C., and was born in 1818. He graduated from the University of Virginia, and selected civil engineering as his profession. He was engaged to survey a projected railroad between Charleston and Cincinnati. He studied medicine and was graduated at the Medical College of South Carolina. He studied several years in Europe, and was sent by President Buchanan to Turkey to teach the Turks the cultivation of cotton. He was appointed by the Turkish government Mining Engineer for Turkey, which place he filled four years. In 1857, he invented the inverted microscope. Returning to America, he was appointed Professor of Chemistry in the University of Virginia.

AMONG THE IRON-WORKERS.—CORNWALL.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: The most remarkable deposit of iron ore in Pennsylvania, at Cornwall, is but six miles from Lebanon, and to see Lebanon without going to Cornwall would be to explore Philadelphia and leave out Independence Hall. The early morning train leaves Lebanon at half-past six, and as the station is about a mile from the hotel, one must rise quite early if he would catch his train. The Doctor was much interested in iron deposits, but not sufficiently so to make him get up at such an hour, so the student had to go alone. The waiter was to wake me at half-past five; but I had the excursion quite firmly fixed in my mind, and was nearly dressed when the knock came. It is scarcely light by six o'clock in winter, and it is something of an undertaking for a stranger to find his way about town. The student was rather precipitous in his movements, but a fall on the ice slightly checked his speed. It was after some inquiry that the station was reached, and the trip actually begun. It had been but a few weeks since the railroad undertook a passenger service, and the arrangements were then somewhat primitive. Until recently, the Cornwall people had to drive in and out whenever they would visit their county-seat. The manager's office is at the North Cornwall Furnace; so I went directly there in order to present my letter of introduction and make out a programme for the morning's sight-seeing. In the kindness of his heart, the conductor put me off at the junction, and told me to follow the track over to the furnace. I started to carry out his directions; that is, I got out of the car and looked at the track to be followed. It was entirely untrodden, and my low sandals offered little protection against the deep snow. The train had moved off when my examination ended, so I had to trudge after it, until I came to a passable cross-road, and then strike out for the furnace office. The manager was not there when I arrived; but when he did come, business only permitted a few words, and I was put in charge of one of his clerks. The North Cornwall Furnace was the nearest object of interest; so that we visited first. There is but one shaft now in blast, but a second one is in course of construction. The engine-house contained two large blowing-engines, and, like Toddie in *Helen's Babies*, there was great fascination in "seeing the wheels go round." The great throbs that smote with a dull sound on our ears and shook the very building seemed like the pulse of the whole works—and so indeed it was; for were it to cease, the vital current of air would no longer keep up the combustion, and the furnace would become a chill, dead thing. This air, which is thus separated from the general atmosphere at so much expense, has no little work to perform: let us follow its course. From the engine, it is forced through the pipe-stove, and only when it reaches a temperature of about 950 degrees is it considered sufficiently hot to be introduced into the furnace. From the stove, the air is conducted in large pipes to the tuyeres, and, as it gains admittance, accomplishes its work of burning the fuel and reducing the ore. The older furnaces were all arranged with but slight blast, and what they had was cold, so that the amount of iron produced was far inferior to the present. Modern furnaces, when forced to do their best—on show-days as it were—are capable of a daily output of three hundred tons, an amount that seems quite marvelous when we consider that it exceeds the *monthly* product of many of its predecessors. But this of course is as remarkable in its excess as the others in their deficiency. The daily output of the Cornwall furnaces is only from thirty to fifty tons apiece. There would seem to be almost a personal element about a blast-furnace, its good or bad behavior to be regarded as a favor or demerit. The workmen become attached to the objects with which they are associated, even though those objects be inanimate. But a furnace seems hardly to belong to this class; for its uniform operations and productions endow it with an apparent vitality. Its life, each minute, is sustained by the powerful blast and generous fuel, and its energy effects the wonderful transformation of stone and ore into the most useful of all our metals. During our inspection, we went up the elevator, or "lift" as the men call it, and watched the process of charging the furnace. As the conical bell is lowered to allow its charge of ore, fuel, and flux to pass into the furnace, a great cone of flame and smoke rushes skyward. A patent "seal" has been invented by Mr. Weimer, in order to save the outrushing gases, but it is not used at the Cornwall furnaces. When our interest and curiosity had been quite satisfied at the furnace, the clerk kindly drove us over to the celebrated Ore Bank. The comfortable little sleigh and spirited horse were quite a pleasing contrast to the manner of my entrance. The bank, about which I had heard so much, was even more extensive than I had pictured to myself; but unfortunately, the snow-covered ground discovered to us only a part of its treasures. In spite, however, of the wintry weather and not infrequent snow-squalls, the miners were kept busy at work wearing away the massive iron cliffs and shipping the ore to the ever-receptive furnace-mouths. The manager's son kindly took me around the property. The railroad extends its various arms to the different parts of the cliff, and we had a very comfortable view of the workings from the cosy cabin of the locomotive. The depth of the deposit has been tried at various places by borings with the diamond drill. The greatest distance that the borers have gone without striking the rock has been three hundred and forty feet. This, however, must not be taken as its thickness; for the direction of the drilling was oblique to the bedding, and would not, therefore, represent its true depth. Many beautiful specimens of minerals have been taken from this bank, and the large cabinet in the manager's office is largely made up of native specimens. The ore, though so abundant, is but of inferior grade, as it contains large quantities of the sulphurets of iron and copper, and must, therefore, be purified from the obnoxious sulphur by a preliminary roasting. The workmen attain considerable skill in judging of the quality of an ore from its appearance and weight. The sorting of the mine's output is done simply by this practical method, and without chemical analyses. One can gain some idea of this remarkable deposit by picturing to himself a series of black and naked cliffs, whose entire contents, without any rejection of intrusive rocks, is gradually removed by the diligent pick of the miner, and of hills growing each year more serrated and rugged as an increasing industry makes continual demands on their bounty. The ore is chiefly magnetic oxide of iron, and is not easily reducible. This, in connection with the fact that the Cornwall furnaces use part anthracite, explains their moderate output.

Much of the ore is consumed in the neighborhood, and it is like-

Digitized by Google

wise sent to Harrisburg, Pittsburg, and other places. Although the deposit has been worked for many years, the supply seems practically inexhaustible. The deposit lies on three hills, and consequently can be worked most conveniently from the intervening valleys.

After thanking my guide, I left him to make my way over to the Bird Coleman furnaces at Cornwall proper. The manager showed me over the works, and gave me some suggestions about correct furnace management. I intended to return to Lebanon in the two o'clock train; but the kind manager would allow no such proceeding, and insisted on carrying me off to dinner with him. Nor did his hospitality end there; for he took me over the old charcoal furnace, and, when I had seen all the interesting points in the place, he kindly put me in charge of a friend who was about to drive to Lebanon. The sleighing was excellent, and the horse far from slow, so that the six miles were quickly passed over, and we found ourselves back in town. The doctor had expected me sooner, so was on the outlook for my return. He looked just a little envious when he saw the sleigh gliding along so rapidly; but I comforted him by suggesting the truth of the old proverb, "The early bird catches the worm." The Doctor is somewhat of an antiquarian, and raves in a mild manner about any thing claiming great age, so I made him still further regret his inactivity by giving him a glowing account of the old cannon and shot that were cast at the charcoal furnace during the war of the Revolution. He would not, however, give me the satisfaction of any audible regret, but then his expression was sufficiently significant.

CARL.

DENVER AS A DISTRIBUTING POINT AND A MANUFACTURING CENTER.

Special Correspondence of the Engineering and Mining Journal.

Denver recently celebrated its quarto-centennial. Twenty-five years ago, "gold-hunters" washed the sands of Cherry Creek, within the present city limits, for the precious yellow metal. They were the first settlers of the Queen City of the Plains. For its first two decades, Denver grew but slowly, and its history was uneventful. But its position made it the key to the Rocky Mountain region; and five years ago, when the discovery of the rich ore-deposits of Leadville gave Colorado mining its great impetus, Denver assumed much importance as a distributing point. Since then, its growth has been rapid and uninterrupted, until now it is not only the distributing point of the Rocky Mountain region, but it is also a manufacturing center of much more importance, perhaps, than Eastern readers of the ENGINEERING AND MINING JOURNAL who have not recently traveled in the West realize.

In the first place, as a distributing point its favorable location has at the same time made it a Western terminus of the great broad-gauge lines of railroad across the plains, and a center from which the narrow-gauge lines radiate to the various mining districts of the State. Of the standard-gauge roads, with Denver either as the terminus of important branches or of the main lines, we have the Burlington & Missouri, the Atchison, Topeka & Santa Fé, the Kansas Pacific, and the Union Pacific. Another trunk line, the Denver & New Orleans, in process of construction, has reached Pueblo, and, when completed, is to give Denver direct communication with the sea-board. Although there is still room for improvement in rates to Denver, these competing lines give to it facilities unapproached by any other city of the region for collecting in wholesale stocks all supplies for the Western markets. Access is furnished to the developed portions of the State by the Denver & Rio Grande, the Denver & South Park, and the Colorado Central, as the most important of the narrow-gauge lines. In the aggregate, they are two thousand miles long, three quarters being contributed by the Rio Grande road. There are but few good districts that they have not already reached, and none to which extensions are not already contemplated. In addition, are two uncompleted narrow-gauge roads, the Denver, Longmont & Northwestern, and the Denver, Utah & Pacific. Thus Denver is seen to possess excellent railroad facilities, unequaled in the West and excelled only by the larger cities of the East.

As to its manufactures, most of the industries which rely upon mining for their support are represented here. Among the well-established machinery firms are Hendey & Meyer, doing an excellent and increasing business. They build engines and boilers for mining and other purposes, engines being a particularly favorite specialty. They also build stamp-mills and all kinds of rolls; their water-jacket lead furnaces are celebrated throughout the West; while ore-cars, slag-pots, and other small yet important accessories to the mining and the smelting industries are turned out in large numbers. Their works comprise four spacious buildings—a machine-shop, a pattern-shop, a foundry, and steam-engine works; and to fill their orders, they are compelled to run their shops night and day for a considerable portion of the year. The proprietors are both practical mechanics, and secure to their patrons a high order of work by giving their business personal supervision. They employ one hundred and twenty men.

Another company, well-known throughout the West by the work it has turned out, is the Colorado Iron-Works. Nearly every mining district, from Mexico to Idaho, has some of its machinery—engines, boilers, pumps, furnaces, crushers, rolls, stamp-mills, etc.—in operation. The capacity is unequaled by that of any similar works this side of the Missouri to the East or the Pacific to the West. The works were established in 1876, and give employment to one hundred and seventy-five men.

A third firm, the Hendrie & Bolthoff Manufacturing Company, long in business here, has gained a wide and enviable reputation. Its pony stamp-mills are very extensively used, its ore-sampling mills used by the largest and the smallest ore-handlers alike, while hoisters and concentrating machinery are also specialties. It also deals in and carries a complete stock of mining supplies at its spacious sales-rooms and warehouse, and has a widely extended trade.

Large shops are just starting by H. N. Nichols & Co., for the manufacture of two specialties—the Sharpneck steam-stamp and the Rouse concentrating-tables. In his steam-stamp, Mr. Sharpneck prevents the shoe striking the die by the automatic use of a steam-cushion, according to the steam-hammer principle. He thereby obviates the excessive jar and wear which have hitherto been the great objection to the steam-stamp. Extended trial has been successful in both of the essentials, durability and economy. The erection of extensive shops for the manufacture of this stamp heralds a competitor promising rapidly to supersede the drop-stamp, so long possessor of the field of milling and concentrating ore.

The Colorado Machinery Company deserves mention. Although its works are in South Pueblo instead of Denver, its Denver house secures to it the advantages of the Denver manufacturers. This company not only builds general mining and smelting machinery, but also carries heavy supplies.

The merchant iron rolling-mills of the Colorado Coal and Iron Company are located in Denver. At the main works of this company in Pueblo, the manufacture of nails is largely carried on. Its Bessemer works and steel rail mills are among the few steel-works of the country whose activity has been unaffected by the abatement of railroad building. At present, with an order from the Burlington & Missouri Railroad which it will require several months to fill, it is taxed to its utmost capacity. The plant consists of two Bessemer converters, each of six-ton capacity; one eighty-ton blast-furnace, and another in process of construction, the steel rail mill, the nail mill, and a foundry. The company owns its own coal mines and coal-fields, and cokes its own fuel. All told, it employs from two to three thousand men. Recently, it has begun the experimental manufacture of spiegeleisen from Colorado ore. The indications are, that it will succeed in making a spiegeleisen that will answer every requirement, although more extended trial will be necessary to completely demonstrate this fact.

Other manufacturers doing an extensive business are F. M. Davis and J. W. Jackson, both builders of general mining and milling machinery; Davis, Creswell & Co., manufacturers of all kinds of brass goods and fittings; and Runkle & Wich, boiler-makers. In refractory materials, the Denver Fire-Clay Company and the Golden Brick Manufacturing Company (works and yards at Golden, Colo.) make fire-clay materials of all descriptions.

In addition to the Denver manufacturers, a number of the large Eastern houses have established Denver branches, where is kept constantly on hand an extended stock of their machinery and manufactured materials. Notable among them are the Pennsylvania Tube-Works, with I. R. Buchanan as agent; and Fraser & Chalmers, represented by L. C. Trent.

In another respect, as a smelting point, Denver is a center of great importance to the Rocky Mountain region. The largest smelting-works of their respective kinds in the country, namely, the Boston & Colorado Smelting-Works, treating gold and silver-bearing copper ores, and the Grant Smelting-Works, treating silver-lead ores, are located here. The Boston & Colorado Smelting-Works, located at Argo, a suburb of Denver, treat all kinds of gold and silver ores, except such as carry a notable percentage of lead, the precious metals being concentrated in a copper matte according to the famous Swansea or South Wales process. It is one of the few Western works which separates and refines the gold and silver. The silver produced each week is sent to one of the Eastern mints in bars 999·8 fine. The gold is sent in bars from 870 to 900 fine. The copper product, after the extraction of the gold and silver, is shipped either to Eastern or to English copper smelting-works in the form of black oxide or as black copper, as either is in most demand. The output of the works for the first three quarters of 1883 was:

Gold	$784,000
Silver	1,846,000
Copper (1052 tons)	345,600
	$2,885,600

It is larger than for any corresponding period in the history of the works.

The Grant Smelting-Works treat free-smelting and lead ores in blast-furnaces by the ordinary Western lead-smelting process. The daily output of five cars of lead bullion is shipped to the Omaha Refinery, which was recently incorporated with the Grant Works under the name of the Omaha & Grant Smelting and Refining Company. The plant in Denver alone treats more lead ore than any other smelter in the country, so that the recent purchase of the Cummings & Finn smelter at Leadville gives the company a capacity far exceeding that of any of its competitors.

Both of these smelting-works get the most of their ores from the mines of Colorado; but large quantities also come from New Mexico, Arizona, Utah, Montana, and Idaho. The excellent smelting facilities of the city have led to the erection of ore sampling-works to which many shippers prefer to send their ores, have them sampled, and then sell to the smelting-works which bid highest, instead of selling directly to one of them. There are at present two in operation, the Colorado Ore Sampling-Works and the Denver Sampling-Works, while a third, the Public Sampling-Works, with a daily capacity of 150 tons, is in process of construction.

The prosperity of the season now drawing to a close may be looked at in two ways. If the aggregate of business done forms an indication, it has been a prosperous season. Shipping mines have been active, and their number is on the increase. As a consequence, machinery has been freely purchased. The ore receipts have been very large with both smelters and sampling-works, especially the past two months, crowding both to their utmost capacity of handling. On the other hand, competition has been closer. With machinery men, the older firms have not done as much business as in previous years, the new supply-houses having come in both for a part of the old trade and a share of the new. The complaint of dull times has resulted. The explanation lies not, however, in the aggregate of sales falling off, but in a distribution of the business between a larger number of firms. If business is not overdone, all the firms may stand. But in smelting, as competition gets closer, the tendency of the weaker works to go to the wall has shown itself. It is not only seen in lead-smelting, by the closing down of two of the Leadville smelters, and the sale of a third to the Grant Company, but in gold-silver-copper smelting also, in the closing of the Miners' Works, at Golden. These works were in operation between two and three years—long enough to prove that a concern with a third of a million capital, in an out-of-the-way place, can not compete with one centrally located, and with six times that amount of capital.

As a city, Denver has, from the latest directory estimates, seventy thousand inhabitants. It is built on the plain gradually rising from the South Platte River toward the east, giving a magnificent view of the front range of the Rocky Mountains. The foot-hills of the range are about twelve or fifteen miles away; but the atmosphere is so clear that

Digitized by Google

the distance seems no more than a third of that. The streets of the city are broad and shady. The buildings are well worthy of the pride felt in them by the people of this new city. The generally cool summers and mild winters are very pleasant. The only objection is the light rain-fall, too light the average season to support a vigorous growth of vegetation. In part compensation, there are few dark, lowering days, making every one gloomy and sullen; on the contrary, the sky is almost always clear and the atmosphere exhilarating. Until the present season, the city has always been troubled about its water supply. Badly filtered water containing alkali has been its curse. Strange to say, people went on year after year using while execrating it, without thinking of a crystal liquid but a few hundred feet beneath the surface. At last, it occurred to some sensible person that the rain-fall on the east side of the front range might supply artesian wells at this short distance. No sooner tried than excellent water was struck, so far without any appearance of being limited in quantity. Since the first strike, about six months ago, a great many wells have been sunk, always with the same result—excellent water and an unlimited supply. Thus has a special objection to the city given place to a strong point in its favor. Few cities have as good water as Denver now has—none could have better.

DENVER, Oct. 20.

MINING AT THE BOSTON EXHIBITION.

Correspondence of the Engineering and Mining Journal.

THE NORTH CAROLINA EXHIBIT.

If the modern Athens had nothing to show the visitor except the North Carolina Department of the American Exhibition now held here, that in itself would amply repay him for the time, trouble, and money spent on his trip here. Occupying the center of the spacious building, it richly merits the attention which its conspicuous position insures it. It is to most people a genuine surprise to see the wonderful diversity and great value of the products of the old North State, showing as it does, in addition to its valuable agricultural products, a great variety of most beautiful building and ornamental stones; woods which fairly captivate the eye; immense, lustrous, and most precious gems; iron ores at once rich and pure in large and thick deposits, and at least in some cases in close proximity to coking coal, limestone, and transportation; copper sulphurets, from the common cupreous pyrites to the chalcocite (copper glance) of the Blue Wing mine; gold quartz with most attractive labels, though of course telling little to the eye; and a wealth of other mineral matter, of great promise—graphite, pyrolusite, chrome iron ore, and others.

But, with its wonderfully rich and varied natural resources, North Carolina is "land poor." It needs both capital and skilled labor to enable it to avail itself of its own riches. In sending this wonderful display to our Exhibition, she has taken a wise step, teaching us by an object-lesson not easily forgotten what great opportunities she offers to our capital and enterprise.

Coal-Fields.—The State has two coal districts, the Dan River, mainly in Stokes and Rockingham counties, near the middle of its northern boundary; and the Deep River District, mainly in Chatham County, near the center of the State.

The area of the Deep River field was estimated by Emmons at 300 square miles. Its principal seam is 6 feet thick, or 7 feet 6 inches, if we include a small bed 18 inches thick separated from the main bed by a layer of shale and black-band iron ore, also about 18 inches thick. The coal is a strongly coking one, swelling and melting in the fire. It is said to be excellent for forge use, for steam-raising, and for gas-making. The coke exhibited made from it is very fair, porous, hard, and quite resonant, apparently equal if not superior to the best Colorado coke in its physical properties, and, if we may judge from the analyses of the coal, much freer from ash and sulphur. The following analyses of the Deep River coal speak for themselves:

COALS FROM DEEP RIVER DISTRICT.

LOCALITY.	Fixed carbon.	Volatile.	Ash.	Water.	Sulphur.	Analyst.
Egypt	63·28	25·74	10·14	0·84	1·35	Genth.
Gulf	70·48	21·90	6·43	1·16	1·02	"
Egypt	60·70	32·70	5·30	....	1·30	Schaeffer.
"	59·30	30·50	10·20	....	....	Genth.
Wilcox, near Gulf	63·30	25·70	10·10	....	1·30	Johnson.
Gulf	70·50	21·90	6·50	....	1·00	Genth.

This coal derives great importance from its close proximity to very extensive iron deposits; most of those given in analyses 1 to 9 inclusive, in the table of iron ore analyses below, being within reasonable distance of it. The occurrence of a considerable bed of black-band ore in the coal itself, and of a bed of the same ore, practically six feet thick closely underlying the coal, is in itself a matter of no small importance.

Of the coal of the Dan River District, not so much is known. It is a dry, semi-bituminous coal, and its appearance is by no means as inviting as that of the Deep River coal. Still, its existence in known beds of great extent and of workable thickness in close proximity to the very important group of iron-ore deposits which contains the Rogers bed, No. 12, in the iron-ore table below, at once rich, perfectly pure, and extensive, assures its value. The area of this coal-field is considerably less than that of the Deep River field, and the greatest authenticated thickness of any of its beds seems to be three feet, though it is possible that at least one of the three chief seams may in places exceed this size.

Iron Ores.—Of these, there is indeed a most imposing array, not less than twenty-eight mines being represented by fine specimens. The western half of the State is well dotted over with valuable iron deposits, most of them wholly untouched. We are told by Professor Kerr that iron exists in workable beds in thirty counties; but for convenience, we may group the greater number of the most valuable known mines into four geographical divisions. First, we have the iron regions of Granville, Chatham, Guilford, and Stokes counties, lying to the north of the center of the State, within reasonable distance of the North Carolina coal-fields, and containing among other valuable deposits the thick and pure Buckhorn, Ore Hill, and Chapel Hill beds, and the extensive series of titaniferous deposits of Guilford County, of remarkable thickness, purity, and richness. Next, we have the deposits of Gaston, Lincoln, and Catawba counties, lying to the west of the center of the southern border, with beds like those of the Big Ore-Bank and of Yellow Ridge, reported to run to a thickness of 16, 18, and even 40 feet. In the northwest corner of the State, in Ashe, Caldwell, and Mitchell counties, is yet another series of beds, the famous Cranberry deposit standing at the head, with its almost fabulous thickness and its entire freedom from phosphorus and sulphur. Finally, in Cherokee County, in the extreme southwest corner of the State, we have deposits as yet but little known, but reported to be very thick.

The ores of these western groups have the advantage of being within a moderate distance of the coal-fields of Tennessee.

In the following table are collected the analyses and thicknesses of some of the more important iron ore-beds of the State. Many of the thicknesses appear to be estimated, and many of them no doubt represent the maximum rather than the average thickness of the beds. The number of beds which are at once rich, pure, thick, and comparatively accessible promises much for the future importance of North Carolina as an iron-producing State:

OTHER IRON ORE-BEDS.

Number	14	15	16	17	18	19	20	21
County	Caston, Lincoln, and Catawba.							Caldwell.
Name of mine	Big Ore.	Brevard.	Robinson.	Morrison.	Forney.	Yellow Ridge.	Castner.	
Location								Near Patterson.
Thickness, feet	Up to 18 feet.	4 to 12.	4 to 12	4 to 12		16 to 40	10 to 20	12 to 15
Authority	Hanna. Several beds.	Hanna.	Hanna.	Hanna.	Hanna.	Hanna.	Hanna.	Hanna.

No. 22, Ashe County, near Helton. 9 and 18 feet in thickness; authority, Hanna.
No. 23, Cherokee County, near Murphy. 10 and 25 feet in thickness; authority, Hanna.

Beds numbered 1 to 9 are near the Deep River coal-field.
No. 12 is near Dan River coal-field.
No. 13 has an outcrop reported to be 1500 feet long; it is near the Tennessee coal-fields.
Nos. 21 to 23 are near the Tennessee coal-fields.
No. 5 is from the Gulf coal strata.

Copper Ores.—Of these, there is an interesting display. The most attractive is perhaps the very rich copper glance of the Blue Wing mine of Person County, very free from gangue, and said to be from three to four feet thick. It should be a most excellent smelting ore, and if the information given about it is accurate, the mine should be of very great value.

Digitized by Google

Of the Gillis mine, in the same county, great things are told. From the adjoining county, Granville, there are fine-looking ores, siliceous copper glance, which appears to be the characteristic ore of this promising region. From the center of the State, the Cid and Conrad Hill mines of Davidson County, and Clegg's mine, of Chatham County, are represented by rich chalcopyrites, with quartz gangue. From Mecklenburg County, near the center of the southern border of the State, come rich solid cupreous pyrites, free from gangue. The celebrated Ore Knob mine, of Ashe County, is not represented.

It is generally known that a large proportion of the North Carolina gold mines, or mines which at the surface carry only gold, grow rich in copper as they approach the water-line, until, in many cases, copper becomes the metal of greatest value. This is especially true of the gold deposits of Guilford, Cabarrus, and Mecklenburg counties, in and to the south of the center of the State. What with the very considerable deposits of copper alone, and with the extension of the gold mining industry in North Carolina through the application of improved metallurgical processes to the refractory ores which formerly defied the arrastra and Chilian mill, this State should at no distant day become one of our chief copper producers.

Gold Ores.—Of these, there is a large display, chiefly of gold quartz, from which, of course, little can be gained by a superficial inspection, although the labels attached to them produce a cheerful impression. Gold is very widely distributed through the State, being found in workable quantities in no less than twenty-nine counties, covering nearly all but the eastern one hundred miles or so. It is generally found alloyed with silver. The greater portion of the more important deposits is situated on a granitic axis which runs northeasterly across the State, passing a little west of its center, from Mecklenburg County, on the south, to Caswell County, on the northern border. We are told of five more or less important gold reduction-works: The Designolle Works, near Charlotte; the Conrad Hill Smelter; the Davis Chlorination-Works, at Salisbury; the Mears Chlorination-Works, near Mount Pleasant, in Cabarrus County; and a chlorination-works near Mount Tucker.

Gold mining is now most actively prosecuted in Davidson County, which is a little west of the center of the State. Besides several smaller mines which are actively worked, we have here the Conrad Hill, which is said to be the best equipped in the State, having an ore which is said to average from $17 to $20, and smelting its concentrates with Connellsville coke. In addition to their contents in precious metals, the concentrates are said to carry from three to thirty per cent of copper. Here is also the Silver Valley mine, said to be turning out ten tons daily, and having, besides twenty stamps, nine buddles and other concentrating apparatus. The concentrates are said to run from $13.30 to $154.28.

Gold mining is also actively carried on in Rowan County. The Reimer mine, near Salisbury, is from four to eight feet thick, and is said to carry from $11.32 to $126.77. The sulphurets are roasted in fixed reverberatories, treated by the Mears chlorination process, and the gold is precipitated on charcoal. The Gold Hill mine, near Salisbury, is estimated to have produced $2,000.000 in precious metals. It has reached a depth of 750 feet, and is provided with twenty stamps and four amalgamating barrels. Its ore is said to carry from $4.53 to $255.71, as usual rather a broad margin, and we are not told nearest which of these two figures the average lies. The Phœnix mine has an ore said to run from $10 to $85. It is said to have chlorination-works for ten tons daily, with ten stamps and three rotary roasters.

In Mecklenburg County, the Baltimore & North Carolina mine has an ore-body from one to four feet thick, carrying from $20.95 to $31.82, besides considerable copper.

In Ashe County, the Copper Knob mine is 135 feet deep, and from 20 to 42 inches thick. Its concentrates are said to carry $79.75 with 37·5 per cent of copper.

In the following table are collected the reported maximum and minimum assays and the present depths of some of the other more important gold mines:

NORTH CAROLINA GOLD MINES.

NAME OF MINE.	Minimum assay.	Maximum assay.	Present depth in feet.
Lalor, Davidson County	$20.00	$190.00	....
Eureka, " "	25.19	1890.00	....
Silver Hill, " "	6.89	26.01	600
Wellborn, " "	10.88	39.20	....
Southern Belle, Rowan County	17.04	49.61	160
Dutch Creek, " "	10.00	30.00	....
Gold Knob, " "	20.60	108.55	....
Clark, Mecklenburg County	8.34	164.44	70
Rudisill, " "	6.20	130.22	300
Ferris, " "	10.34	512.94	....
Simpson, " "	3.79	70.89	....
Stephen Wilson, " "	4.52	355.96	....
Black, " "	50.16	488.12	....

The first gold mines in the United States were those of North Carolina, and, prior to the discovery of California, the largest nugget of gold ever known was found within its borders, in Cabarrus County, reaching the then fabulous weight of twenty-eight pounds. Had any thing like the energy and intelligence that have so wonderfully developed the resources of California been concentrated on the gold deposits of North Carolina, the treatment of the precious metals there would have been to-day an industry of colossal proportions.

Building-Stones.—There are few things in the Exhibition which so charm the eye as the many and beautiful building-stones in this display. Perhaps the most striking is the beautiful leopardite, from Mecklenburg County, with spots stained with pyrolusite and black as ink, prettily distributed over a nearly white ground. There are two marbles exhibited which deserve the highest admiration—a beautiful flesh-colored marble, from Red Marble Gap, and a delicate gray marble from Valley River. The former is fine-grained, and of a color which rivals the *giallo antico* of Italy in beauty and softness, although of a very different hue. Its tint is really most charming. The latter is of a uniform, very delicate gray, and almost as fine as the Italian Carrara marble, and as beautiful. From Patterson, comes a large block of dark serpentine, highly polished, and of a wonderfully rich deep luster. Perhaps the most beautiful block of granite I have ever seen is here exhibited, from Wadesboro'. It has two beautifully colored feldspars, one pink, the other greenish, with a deliciously transparent yellowish quartz, and a sprinkling of black mica. Besides this, there are several other beautifully polished granites, a very handsome black one from Wanesboro'; a red syenite from Cedar Rock, with a very fine grain; and, what is more striking than any of them, a very strongly marked orbicular granite from Davis County.

Cabinet Minerals.—There are several cases with most fascinating displays of cabinet specimens; crystals of emerald of fabulous size; beautiful hiddenites and smoky quartz crystals, some of the latter with basal planes; gummites of surprising size; enormous mica crystals; sheets of mica perfectly transparent, and as white as any glass; well-shaped garnets over six inches across; and many other rare and beautiful minerals. Truly this must be a mineralogist's paradise. H.

THE PROGRESS OF BILBAO.

The extensive works for the improvement of the port of Bilbao have now been finished, and it may be said that they are most successful. Formerly, the depth of water at the sand-bar, near the entrance to the harbor, was not more than 15½ feet during the spring tides, whereas it now reaches a depth of 23 feet and upward; so that the enormous difficulties attending shipment have been entirely overcome. This has been accomplished partly by the dredging of the river-bed, and also by the erection of an iron screw pile training jetty across the bar. At present, it can not be ascertained how far these improvements will affect exportation of ores, which has steadily increased since the termination of the Spanish civil war. In 1878, the exports amounted to 1,244.118 tons; in 1879, 1,167,138; in 1880, 2,279,225; in 1881, 2,428,936; in 1882, 3,439,674; and in 1883 (up to August), 2,082,487. Despite the general depression which has prevailed in the iron and steel trades since the beginning of the year, the export of ore has been well maintained. Again, the prices of Campanil and Rubio ores, f. o. b. Bilbao, have scarcely fallen, a circumstance which may appear surprising, but for which several reasons may be cited. In the first place, property which some years ago was in weak hands, has been gradually passing into the possession of a few owners whose financial position is invariably sound and reassuring, and who, of course, do not need to make compulsory sales. Further, the cost of working has been increased by reason of the scarcity of labor, no accommodation having been provided for the workmen.

It is not our intention, says *Stahl und Eisen*, to inquire whether the province of Viscaya, especially the vicinity of Bilbao, offers a favorable situation for the development of a Spanish iron and steel trade. No doubt there are many favorable conditions; but on the other hand, there are some important drawbacks which can not be ignored. Efforts have been made to smelt the ore at the place itself, and these endeavors have found expression in the erection of new and the enlargement of existing works. Besides the old works of Ybarra y Ca., the English Company of Cantabria began the erection of two blast-furnaces on a most favorable site near San Nicholas. But the company came to grief, and was eventually obliged to suspend operations. The partially erected buildings went into the hands of the Marquess de Mudela, who finished the two blast-furnaces and added two others. This plant has been working for two years and a half, and it produces monthly about 8000 tons of Bessemer and foundry pig-iron of excellent quality. During the past year, the works of Ybarra y Ca., were transferred to the Sociedad de Atlas Hornos y Fabricas de Hierro y Acero. Besides the three blast-furnaces belonging to this company, it is intended to add some others shortly. The main purpose of the company is the manufacture of railroad material, but it seems probable that the works will extend their operations to all sorts of rolled merchant iron. The capital of the company is divided into 25,000 shares, of £20 each, and the concession lasts for seventy-five years. Besides this, 25,000 bonds, of £20 each, are to be issued, and will bear interest at the rate of three per cent. The total capital of the company amounts to £1,000,000.

Another company, the Viscaya, has also been formed, with the intention of erecting blast-furnaces and Bessemer plant. There is little hope, however, that the works will be started before 1885. This company's capital is fixed at £410,000. The company has arranged with Cockerill, of Seraing, to build two blast-furnaces, each 75 feet high, and of 20 feet diameter, and with a capacity for a daily production of 100 tons. Adjoining is a large dock which is in direct communication with the river.

It is estimated that these three works, when finished, will produce together about 250,000 tons of crude iron annually. The production of crude iron, as well as railroad material, is intended to satisfy the Spanish market; and there can be no doubt that, under the present protective system, the prospects of the companies are favorable.

From the foregoing, it will be gathered that, great activity prevails in the Bilbao District, and that the improvement effected in the harbors augurs well for the future of the port.

THE BICYCLE COEFFICIENT OF SAFETY.—Very little is allowed to escape the inquiring mind of investigators nowadays—a fact which has been strikingly illustrated by a series of able researches. Lieutenant F. I. Drake, U. S. N., has written a very interesting paper on the bicycle co-efficient of safety, his object being to ascertain the conditions under which there is the greatest security against "headers" without materially sacrificing speed. He gives a table of the mechanical force for different velocities and different weights, which ought to convince any reasonable rider, when an accident has happened, that damages to his wheel are not due to defective material or faulty construction. He then investigates the important subject of the rake of wheels, and finds that the expert Columbia is the closest built wheel, the rake for a 54-inch wheel being two inches, although the average loss of weight force does not exceed four pounds. The percentage of gain in the coefficient of safety for the Columbia wheel is found to be increased four per cent by the proportionate rake, while the corresponding loss of mechanical energy to propel the wheel is two and seven tenths per cent, showing an advantage of one and three tenths per cent in favor of the rake as adopted by the Columbia Bicycle Company.

ON DIFFERENT SYSTEMS OF HYDRAULIC CRANES FOR STEEL-WORKS.*

By R. M. Daelen, Duesseldorf.

Among the hydraulic apparatus which are principally introduced in the mechanical installation of steel-works, the hydraulic crane takes the most important place, because the capacity of production of a steel-works is in a great measure dependent upon the capacity and solidity of the cranes. In order to appreciate the various systems applied to the different purposes of steel-works, it is necessary to study the different methods of construction employed in practice since the introduction of the Bessemer process. The different purposes for which cranes are used in a Bessemer steel-works are the following:

1. Each pit has a center crane to carry the ladle after the pouring of the converter, and also for casting the steel in the molds. For the latter purpose, there is often also a second crane.
2. Outside of the pit, there are a number of cranes to place the molds in the pit, to lift them up with the ingots, and to transfer these to the bogeys.
3. There are also cranes serving different purposes, such as changing the ladles, distributing the ingots, etc.

The question of security against fracture is in all cases of the utmost importance.

The first condition for the efficiency of the center crane is that of facility of movement and exactness in stopping over the middle of each mold.

The usual system is that shown in Fig. 1, and the difficulty of fulfilling the conditions stated increases with the length r of the jib. The friction of the rolls R and the pivot Z is dependent on the proportion: $\frac{Pr}{a}$ The length of the measure a is limited, because the ram M must be cast in one piece. This is the reason that the measure of $r = 18$ feet is not generally exceeded; and although there are performances with $r = 23$ feet, it is undeniable that in this direction an improvement would be of advantage. It is possible to do any thing by the balance-weight g, and there is no scruple about making it very heavy, because, in relation to the total weight to be lifted, the section of the ram M is too large, being calculated for the resistance; but with the moment of turning, the difficulty of stopping the movement of the crane becomes apparent. For the improvement of the center crane, it is not necessary to insist upon the economy of using hydraulic power, because this apparatus does not make more than three or four lifts per operation—that is, 90 feet, or 200 in twenty-four hours; and this circumstance seems to indicate the reason why, in this direction, we find less endeavor at improvement than in the arrangements of ingot cranes, of which the number of lifts may vary from 1000 to 2000 in twenty-four hours. The best way to obtain suitable conditions for a center crane is to apply it mainly for the pouring of the converters and to use another apparatus to carry the ladle while casting the steel in the molds.

The principal conditions required in the construction of ingot cranes are:

(*a*) Great quickness in moving up and down.
(*b*) Facility in turning by hand.
(*c*) The greatest economy in the use of hydraulic power.
(*d*) The lowest minimum of repairs.

These conditions are not all fulfilled by the crane with the simple ram shown in Fig. 2, because (*a*) the total weight to be carried is too great in comparison with the charge. (*b*) There is a considerable friction sideward between the ram and the cylinder, and also in the stuffing-box. (*c*) The consumption of water is too high in proportion to the charge P, the diameter of the ram M being calculated for the resistance to bending, and the weight of the falling parts being greater than the charge P. (*d*) The use of packing material in the large stuffing-box is very considerable. Sir H. Bessemer, as I am aware, was the first to employ the principle of the differential ram (Fig. 3), by which the consumption of water was considerably diminished; but to this arrangement there is the objection that the second stuffing-box is situated underground, and therefore not easily available for observation and repair, so that this system has not been very often adopted.

In the year 1873, Mr. R. Daelen, Sen., found that attaching the ram to the pillar and moving the cylinder was attended with many advantages (Fig. 4). In the system shown in Fig. 3, it was not possible to cast the ram (M and M) in one piece, and so the second piece M is to be considered as indispensable; but this is not the case in Fig. 4, because the ram is shorter for the length a, so that there are, in fact, two guides, $g^1 - g^2$, and it is possible, for greater security to fix the top of the pillar on the walls of the building by three or four bars of iron.

The cylinder being less heavy than the ram, there is here a further saving of water, and this system seems to fulfill all the conditions required in practice. As introduced in several steel-works in Germany, it secures good results; but there is the objection that the great stuffing-box shows considerable friction after having worked for some time. The reason of this is, that the measure h being only 3 feet or 4 feet, all the dust going out of the pillar enters into the packing, and so into the cylinder, where it is not taken away by the water as in the systems shown in Figs. 2 and 3. In the most recent application of this system, the measure h has been made higher, and the pillar has been made from hammered steel, bored out in the under part, so that the diameter is less, and hence the crane is more easy to turn.

One of the most interesting arrangements of ingot-cranes is that of the patented system of Messrs. Tannet, Walker & Co., of Leeds, shown in Fig. 5.

In this system, the main casting A is bored out in the center, to receive the ram or pillar B, and also on each side for the two hydraulic rams C and D, one of which is of such an area as to nearly counterbalance the weight of the center ram B with the jib and the balance-weight E; in short, the whole of the falling parts. Of course, sufficient margin is left for the crane to lower when the attendant who commands the other side ram by means of a valve applies the said valve to exhaust the water of the first-named ram, and turn it back into the accumulator. The important consideration of saving water-power is fulfilled here in a very rational manner, and numerous applications have proved it in practice.

* A paper read before the Iron and Steel Institute at Middlesborough.

If there is any objection to make in reference to this plan, it is, that the pillar B can not be greased in its course, because it can not be rid from the dust which collects on it. It may also be that the pressure upon the two side rams is not equal; for instance, when the hydraulic pressure is varied, as is the case where an accumulator with compressed air is used, or where the section of the pipes is not sufficient. In the first case, it may be that the pressure varies from 17 to 25 atmospheres, and then the ram, having to leave the charge, has to be calculated for 17, while the other balances the falling parts for 25 atmospheres. In this case, the saving of water-power would not be very great.

It must also be remarked that the weight of the falling parts is the greatest objection to all the known systems of hydraulic cranes; and this must be surmounted by a corresponding pressure of water to give the rapidity of action which is demanded.

Another system of cranes, known as the American system, is based upon the principle of making the weight of the falling parts as little as possible, so as to diminish the consumption of water and all liability to friction.

Every system of isolated standing cranes requires a very strong ram or pillar to meet the overturning moment Pr upon the foundation. This is not the case in the ordinary foundry crane (Fig. 6), which has a second support at the top, afforded by the roof of the building. In the American system (Fig. 7), the foundry crane is put on an hydraulic ram, and the top support is changed in a guide, so that the whole structure can move up and down. In both cases (Figs. 6 and 7), the thrust Q is $= \frac{Pr}{h}$; and as Q is the same, the ram M is only required to provide for this and not for Pr, as in the case of the isolated standing crane. The sideward friction between the ram and the cylinder is also reduced in the same proportion. As the balance-weight is not requisite, and the upper part of M is made of wrought-iron, the weight of the falling parts of this crane is very little, so that a highly economical use of water is obtained in this way.

This arrangement would be also cheap in installation, if the second support did not demand a construction of roof strong enough to resist the thrust Q, and also the vertical thrust R, caused by the friction of M in the guide-rods. It is also to be observed that, if there is any little change in the situation of the building or the roof, the cranes supported by these must be regulated accordingly. The system, moreover, is not capable of being applied in existing buildings where the roof is not strong enough, nor in the open air.

As, however, the principle of this crane is a very rational one, I endeavored to apply it to an isolated standing crane. For this purpose, the thrust Q is to be applied to the cylinder, because it is possible to make it strong enough to translate the movement Pr to the foundation without augmenting the consumption of water. This is done by the arrangement Figs. 8 and 9. The cylinder A is fixed on the foundation, and bears the cap B on which the rolls C are fixed, these serving to fill the space between A and B, so that the last can be easily turned. The girders E are fixed on the cap B, and serve to transfer the push Q on the cylinder A. The jib of the crane is attached to the ram F by a pivot, and transfers the push Q on the girders E by the rolls D, on the axles of which the bars H are fixed.

The ram has no side friction, and the turning friction in the stuffing-box is avoided. The rolls are in the best possible condition, because they remain dry, and it is not difficult to protect them against dust and dirt, so that the friction of all the movements is reduced as much as possible.

The weight of the falling parts is not so high as in the American system, and it becomes possible to fix the top of the crane to the walls of the building by three or four simple iron bars T, which should, however, only be done to augment the security of structure. I think that this system will fulfill all the conditions required in practice, to the fullest extent possible and in the most simple manner.

For very heavy cranes, a balance-weight can be added in such a manner that it need not augment the weight of the falling parts by attaching it to the girders. This serves to diminish the friction of the turning movement, which is its duty, because the ram has no side friction.

The following table contains a comparison of the different systems of ingot cranes—principal measures and relations:

Hydraulic presssure	20 to 25 atmospheres.
Charge to be carried	3 tons.
Weight of falling parts	?
Consumption of water per stroke	?
Length of jib	20 feet.
Length of stroke	8·25 feet.

	Weight of falling parts. Tons.	Consumption of water per stroke. Liters.
Diagram 2	3·90	211·0
" 4	3·00	137·5
" 5	4·40	71·8
" 7	1·30	95·0
" 8	1·10	78·5

I have to add that I find that for the jib of an ingot-crane a single girder is the best arrangement, being about a third lighter than two of the same strength, and permitting of only one roll to the traveler, which is more easy to move than two or four. The roll, moreover, should not have borders, being guided sideward by the four rolls. Notwithstanding that the diameter of the roll is very large (about 15 inches to 18 inches), there is no danger of reversing the traveler, because the charge will hold it down, and it travels more easily than the other systems referred to.

MESSRS. HELLER & BRIGHTLY, of Philadelphia, have just issued a little book entitled *Remarks on Engineers' Surveying Instruments*, which many will learn to prize, as it contains, besides indorsements of the instruments of the makers by prominent engineers, and extracts from the technical press, in themselves valuable, a number of very useful tables. Among the latter, we note one giving the variations of the magnetic needle. The special novelty of this catalogue is the skeleton transit and level, with all the parts in detail, so that if an engineer wishes to refer to or order from the manufacturer any special part, to replace a lost or worn one, he can do so understandingly.

NEW PUBLICATIONS.

THE MINERAL RESOURCES OF THE UNITED STATES. Published by the United States Geological Survey, J. W. POWELL, Director; ALBERT WILLIAMS, Jr., Chief of the Division of Mining Statistics and Technology. Washington. 1883. 8vo, pages 813. (*With Index.*) Price, 50 cents.

In spite of the facts that the aggregate of the value of the product of the mines in the United States is greater than that of any other country, and that with rapid strides it is in many other branches overtaking older rivals, we have not, until recently, possessed a bureau which collected the figures marking our march of progress, except so far as the two precious metals were concerned. In every civilized country, the department of mines of the government collects annually statistics of production with more or less painstaking care, and in some instances with reasonable promptitude. Hitherto, in the United States, private enterprise has alone attempted to fill the gap. In some branches, the collection of statistics has been brought to a degree of perfection which may serve as a model to government work anywhere, Mr. James M. Swank's records of the statistics of iron and steel being the most prominent example. The press has made strong efforts in the same direction, in some cases with marked success, while in other industries—for instance, in bituminous coal mining—the only reliable data collected are those of State inspectors or the reports of shipments by railroad or canal. No one will be more ready to concede than those who compiled these figures that at best they are estimates only, and their chief value is, that they furnish, at as early a date as possible after the first of January, an approximate notion of the output. Major Powell, the Director of the United States Geological Survey, deserves great credit for having caused the first well-organized effort to be made to establish a bureau of mining statistics, and the work now before us is the outgrowth of its first year's work. It is only just to the survey and to Mr. Albert Williams, Jr., the Chief of the Division of Mining Statistics and Technology, to say that work was only begun in the early months of the year, and that, in spite of the facts that the entire division had to be organized, and that correspondence over so wide an area as the United States is naturally tedious, the whole of the work was ready for the printer's hands early in July. We are anxious to insist upon this point because it proves that, under Mr. Williams's efficient management, the department is capable of putting before the public the results of its investigations within the first quarter of the year, provided there is no red tape at the printing-office to interfere with its business-like methods. From a practical, commercial point of view, every day, every week, saved in the time of publication is of the greatest value, and it is gratifying to know that in this respect the survey has shown that it is capable of meeting the demands of the country. We do not believe that, considering all the circumstances, any reader of this large volume will deny that the attempt to establish a division of mining statistics and technology has been completely successful, and we trust that the funds will be more ample and will be forthcoming more promptly in the future, so that it may be carried to that state of efficiency which it promises to attain under the present management.

The work of organizing and editing has been done by Mr. Albert Williams, Jr., who has been also the principal contributor. For the statistical department, he has gathered about him a corps of specialists of acknowledged standing, like James M. Swank, for iron; S. H. Stowell, for petroleum; J. B. Randol, for quicksilver; Charles A. Ashburner and F. E. Saward, for coal; C. Kirchhoff, Jr., for lead, copper, and zinc; Otto A. Moses, for phosphates; and George F. Kunz, for precious metals; Messrs. C. G. Yale, of San Francisco, and F. F. Chisolm, of Denver, having special charge of collecting data on a number of subjects in the Pacific and Rocky Mountain divisions respectively. On technical subjects, there is a series of excellent papers by such authorities as James Douglas, Jr.; and Dr. E. D. Peters, Jr., on copper; Eugene A. Smith, on the iron ores of Alabama; O. H. Hahn, on lead; F. L. Clerc, on zinc; Prof. W. P. Blake, on nickel; F. W. Taylor, on cobalt; Daniel T. Day, on manganese, chromium, and tungsten; F. A. Wilber, on clays, marls, and apatite; Henry Gannett, on abrasive materials; E. W. Hilgard, on the salines of Louisiana; John A. Walker, on graphite; while among the special contributions, we find a paper by Dr. R. W. Raymond, on the divining-rod, and a paper on electrolysis in the metallurgy of copper, lead, and zinc by C. O. Mailloux, and a note by Prof. W. C. Kerr on the minor materials of North Carolina. A very useful addition to the work is an elaborate series of tables of the localities of the useful minerals of the United States, compiled by Prof. John C. Smock, Whitman Cross, Joseph Perkins, and D. B. Huntley.

It would lead us too far to attempt a critical review of the work of this array of contributors, among whom Mr. Williams takes a prominent place in his admirable review of the salt trade and other industries embraced in the general title of "structural materials." We have already printed some of the papers in full, and shall present others at a later date. We congratulate the survey, and Mr. Williams in particular, on the excellent manner in which the labors connected with this publication have been carried out, and feel convinced that they will meet with the appreciation and indorsement of the mining and metallurgical industries of the country.

PRODUCTION OF GOLD AND SILVER IN THE UNITED STATES FOR THE YEAR 1882. By the Hon. HORATIO C. BURCHARD, Director of the Mint. Washington. 1883. 8vo, 873 pages. (*With Index.*)

Mr. Burchard's figures for the production of the precious metals in the United States have as usual been given to the public in the form of a summary during the early months of the year; and the fact that his letter of transmittal bears date February 21st shows that they were compiled many months ago. The volume contains the usual review of the mining operations of the different States and territories. Some of them, as the report of Messrs. E. F. Burton and J. R. Hardenbergh, of the San Francisco Mint, possess great value, and may be safely accepted as standards for other departments of the work. The review of mining in California is evidently prepared with the greatest care, with less reliance on a mass of clippings from local newspapers, and with more critical judgment. It is only just to say that other parts of the work show evidences of an improvement which justifies the hope that future efforts will be better directed and the data obtained be more closely scrutinized. Mr. Burchard has succeeded in obtaining the assistance of such local authorities as Mr. O. J. Hollister, of Salt Lake City, for Utah; John W. Eddy and R. B. Harrison, of Helena, for Montana; and H. Silver, of the Denver Mint, for Colorado. Mr. A. M. Lawver, of San Francisco, has personally visited the leading mining districts of Arizona, and is responsible for the greater part of the report for that territory. The first part, chiefly descriptive of progress in the mining districts, comprises 648 pages. We believe that it could be conscientiously cut down to one half that length without very serious injury to the value of the report.

The second part, General Statistics, gives a record of the work of the mints and the production of individual mines.

The third part, Miscellaneous, is largely a very indiscriminate jumble of extracts from newspapers, supposed to have a bearing on the technical working of mines, mills, and smelting-works. Among them we notice with much regret, as a prominent one, the *Mining Journal*, which the compiler of this "miscellaneous" section evidently believes has some standing in the technical department of mining. For his instruction, we may state that most of the new and surprising methods which annually grace the pages of our English contemporary, and are gobbled in good faith by some of its younger imitators in this country, are simply abstracts from the British patent records. Imagine a technical journal in this country giving currency to every wild metallurgical scheme put forth by so-called inventors. We do not believe that it is the province of the Mint to attempt to disseminate knowledge on technical subjects relating to the production of the precious metals by reprinting articles, from whatever source they may come. It can command and should be able to obtain original contributions by the best talent, which would be quoted with cordial approval by the mining community.

THE LEADVILLE SMELTERS—REGULATIONS FOR THE PURCHASE OF ORES.

The Leadville smelters have issued the following circular, dated Leadville, October 11th, 1883, which explains itself:

TO MINE OWNERS AND MINE MANAGERS:

We, the undersigned, engaged in the business of purchasing and smelting ore, having arrived at the conclusion that the methods of assaying and settling for ores heretofore existing are vexatious and often unjust, have agreed that, on all contracts made after this date, the following rules will be strictly adhered to:

First. Assays shall be made by standard scorification.

Second. Moisture shall be determined by our assayers, and no splits shall be recognized.

Third. In silver assays, contents shall be noted only in full and one half ounces, that is, every fraction under one half ounce shall be left off, and every fraction over one half ounce shall also be omitted.

Fourth. Gold in ores shall be noted in pennyweights only, no payments to be made for less than one tenth of an ounce contents per ton.

Fifth. In lead assays, fractions of units shall not be noted, and no payments shall be made for less than five per cent contents per ton.

Sixth. The splitting of assays shall be discontinued, and settlement made on our assays if within one ounce of silver, one twentieth ounce of gold, and one per cent of lead of control assays. If a difference of more than one ounce of silver, one twentieth ounce of gold, or one per cent of lead exists, the umpire sample shall be assayed.

Seventh. No person shall be allowed to serve as umpire unless in the employ of the smelting-works subscribed hereto, or in the employ of the mines.

Eighth. In case it shall be necessary to employ an umpire assayer, the mine-owner or manager shall have the privilege of selecting an assayer from among the smelter assayers. Should the mine-owner or manager prefer to have his ore umpired by a mine assayer, then the smelter shall have the privilege of making the selection.

The Pueblo Smelting and Refining Company by A. W. Geist, General Manager.

THE ELECTRICAL TRANSMISSION OF POWER.—*L'Electricité* gives the following account of M. Marcel Deprez's experiments at Grenoble, which we referred to in a recent note: The generator was placed in the cement-works of Messrs. Damaye & Co., at Vizill-Gare, where a turbine of 80 horse-power is in use. A double silicon bronze wire of ·002 meter diameter was fitted upon ordinary telegraph-poles along the road leading to Champ-Vizille, a third wire of brass serving for telephonic communication. The distance between the market-house at Grenoble and the Damaye works is eight miles 1230 yards. In the market-hall, a small workshop has been set up, in which are an endless band-saw, a circular saw, a printing-press, a Dumont centrifugal pump, etc., all of which are arranged around the receiver. This latter is the same that was used at Munich, but has been repaired. This time, M. Marcel Deprez has endeavored, if not to suppress, at least to greatly diminish, the effects of the distance to be traversed by increasing the electro-motive force, hoping to lessen the dangers of so doing by the insulation of the apparatus. He obtains this result by increasing the length of the wire on the machine, and diminishing its diameter. On the first evening, when the public was admitted by card, it was somewhat disappointed to see only the centrifugal pump at work. This raised 1200 liters of water, and formed a cascade which had a pretty effect. The speed of the generator at Vizille was about 600 revolutions, and it absorbed nearly 14 horse-power. On the Sunday, the committee appointed to make an official report verified the result at Grenoble to be 7 horse-power measured on a Prony brake; and at this time the speed of the generator at Vizille was 1257 revolutions, and it absorbed from 45 to 50 horse-power, which corresponds to a return of 15 per cent.

THE ELECTRIC CONDUCTIVITY OF METALS.

In a communication by Mr. Killingworth Hedges, on the fire risks of electric lighting, the following facts were submitted: The conductors must be properly proportioned for the current they have to carry; whatever resistance there is in the conductor will cause a corresponding development of heat, which will vary with the amount of electricity passing, and inversely as the sectional area. The material must be free from impurity, otherwise an impure section will increase the resistance. The extraordinary difference in the conducting power of a sample of "commercial" Rio Tinto copper wire, as compared with the pure metal, was shown in an experiment by Dr. Matthiessen—the conducting power being only 13·6, as against 99·95 for pure copper. The continued heating of an impure metallic conductor has a certain effect on its electrical resistance. With the sample just mentioned, the conducting power at 100 degrees Cent. decreased from 13·58 to 13·558 after the wire had been heated for three days. It does not always follow that there will be a decrease in the conducting power, as with alloys the opposite effect is produced. A copper-silver alloy showed an increase of ·264, after having been heated to 100 degrees Cent. for three days, and a tin-copper alloy an increase of ·13.

As the temperature in Dr. Matthiessen's experiments was not increased over 100 degrees Cent., the author has made some further experiments—heating the wires by the electric current from a secondary battery to within a few degrees of their melting-point. The following materials were tried, the wires and foils having such sectional area and so arranged that, on the current being increased by 20 per cent, they were immediately fused. The total length of each experiment was twenty-four hours, during which time the current passing through varied slightly, and the following is a mean of the results:

Material.	Resistance before heating. Ohms.	Resistance of leads. Ohms.	Difference after 24 hours.
No. 1. Commercial tin wire.....	·815	·8	—·003
" 2. Lead, soft.....	·835	·8	—·005
" 3. Copper, soft	·810	·8	No change
" 4. Pure tin-foil	·860	·8	No change
" 5. Tin and lead alloy...	·870	·8	—·160
" 6. Albo alloy, in foil.....	·835	·8	No change
" 7. Aluminium and tin alloy.....	·820	·8	+·0008

The resistances were in all cases taken at the temperature of the air, which averaged 69 degrees. The sign — shows that the metal decreased in resistance, and + that it increased after continued heating. Nos. 1 and 3, tin and copper, were found to scale when heated. A change has been noticed where high-tension currents have been sent through a pure copper wire for some time—the wire in the armature of a Siemens machine which came under the notice of the author appeared to be brittle, and gave a fracture unlike pure copper.

THE RIVERDALE EXPLOSION.

Writing to *Science*, Prof. Robert H. Thurston says: The boiler of the steamer Riverdale exploded on the 28th of August, a few minutes after the boat had left her wharf at New York, and started for her destination on the Hudson River above the city. Several lives were lost, and the boat itself was sunk in sixty feet of water. The boiler was raised and placed upon the wharf near the Delamater Iron-Works; and the boat, a worthless wreck, was towed to the New Jersey side of the river.

The steamer had two "flue-boilers" 25 feet (7·6 m.) long, 6 feet 4 inches (1·93 m.) in diameter, containing four "direct" flues 14 inches (0·36 m.) in diameter, two of 9 inches (0·23 m.) diameter, and five "return" flues of 11¼ inches (0·28 m.) diameter. The shell was of No. 3 iron, and the area of heating-surface was 676 square feet (63 sq. m.). The iron was of good quality, and was in good condition throughout, except along the bottom, where it gave way. The form, proportions, and workmanship of the boiler were good. The builders, Messrs. Fletcher & Harrison, of New York, were among the most reputable constructors of engines and boilers in that city, and were noted for doing good work.

On examination, it was found that the bottom was corroded along its whole length, and had been patched in a number of places where the iron had become dangerously thin, and that in some places the sheets were reduced to one fourth their original thickness. The shell had been repeatedly patched, and five "soft patches" were found on the girth-seams. The rupture seems to have started in the thin parts of the bottom, and to have followed the weakened girth-seams quite around, and divided the mass into two parts of nearly equal size, tearing the middle sheet out of the shell entirely.

A coroner's jury made an inspection, examined such witnesses as could be found and such experts as could be induced to testify, and rendered a verdict to the effect that the boiler ruptured in consequence of the weakness of the sheets on the bottom of the shell, which were unable to sustain the working pressure allowed by the United States inspector; which weakness had been produced by corrosion on the interior, due to the action of the feed-water. It was further asserted, that the boiler was tested in June up to a pressure of 62 pounds (5 atmos. abs.), and burst ten weeks later under a pressure of but 32 pounds (3 atmos.), in consequence of the neglect of the inspector to observe its condition at the time of testing it. The engine-driver and the inspector were censured by a vote which was not unanimous. The jury expressed the opinion that the present law is not sufficiently explicit and mandatory, and that the use of the test by hydrostatic pressure is insufficient to detect and reveal such defects as here existed.

The inspector acknowledged that he did not try the strength of the boiler with the hammer, as is now usual in all thorough examinations by competent engineers, but merely looked it over; and that at previous inspections he had not entered the boiler, but had only looked in at the man-hole. The evidence of the most superficial and inefficient "inspection" was conclusive; and the fact that proper inspection would have revealed the dangerous condition of the boiler was equally well proved. The so-called "inspection" was a farce; and the inspector, in a spirit of indifference or indolence, took the chances of an explosion.

The exploded boiler weighed 27,000 pounds (12,247 kilos), and contained 25,000 pounds (11,340 kilos) of water. The explosion was not remarkably violent, but was what old engineers are accustomed to call a "burst," rather than an explosion. The consequences were, however, sufficiently serious. The energy producing the effects seen in the case of a true explosion may be imagined, when the amount of heat-energy stored up in such a boiler is calculated. The quantity of heat transformed into mechanical energy by a mass of water and of steam of such magnitude, set free, and expanding down to the pressure and temperature of the atmosphere, from the pressure and temperature at which it existed in the boiler of the Riverdale, would amount to above 1,500,000,000 foot-pounds (over 200,000,000 kilogrammètres). This would be sufficient to throw the boiler and its contents, were the heat all utilized, as in a perfect steam-engine, five miles high. This may give some faint idea of the enormous forces at work, and the tremendous energy stored in a steam-boiler, even where the pressure of the steam is very low, as it was in this case.

It will be concluded, from what has been above stated, that a steam-boiler of the most ordinary and least dangerous type has stored within it an inconceivable amount of available energy in the form of heat, which may be at any moment transformed, in part, into mechanical energy with terribly destructive results, both to life and property; that this powerful agent for good or for evil can only be safely utilized when the utmost care, intelligence, and skill are employed in its application, and in the preservation of the vessel in which it is inclosed; that the present code of law relating to the care, management, and inspection of steam-boilers is entirely inadequate to insure safety; that the inspection of steam-boilers, as at present practiced by the employés of the government, is not only liable to be inefficient, but is likely to prove worse than none, as it gives to the owner, and perhaps often to the man in charge of the boiler, a feeling of security which is entirely without basis in fact, and which may therefore cause the neglect of that watchfulness which might otherwise prevent accident; that simple pressure produced by the test-pump, as now provided for by the law, is not a sufficiently effective method of detecting weakness in the boiler, or to be relied upon to the exclusion of other better and well-known methods of test.

The fact that the hydrostatic test is not conclusive as to the safety of a boiler has long been well known and admitted among intelligent engineers. The steam ferry-boat Westfield met with precisely such an accident a dozen years ago; and it was shown at the coroner's inquest, at which the writer assisted that official in the examination of his expert witnesses, that the boiler had been inspected, and had been tested, but a few weeks before, by the United States inspector, who applied a pressure considerably in excess of that at which the explosion took place. The cause of the accident, by which a large number of people lost their lives, was precisely that which caused the explosion of the Riverdale's boiler, and the method of rupture was the same. In each case, proper methods of inspection would have saved the lives of the sufferers.

It is undoubtedly true, that many of the inspectors are conscientious, experienced, skillful, and painstaking men, and do their duty in spite of the defects of the existing law; but it is also true that now and then a careless or incompetent inspector will neglect the simplest details of his work, and that we must expect occasional repetition of this sad experience, until the law is intelligently framed, and so administered that the passing of a defective boiler by the inspector shall become as nearly as possible an impossibility.

A NEW METHOD OF MEASURING THE DEPTHS OF SHAFTS.*

The following method of measuring the vertical depth of a mine shaft was adopted in 1880 by Mining Surveyor Gräfe, of Bernburg. Three men are employed; two of whom stand on the safety-roof or bonnet of the cage, while the third is seated in a chair fixed to the drawing-rope, about 35 feet above the cage. The attachment is formed by a flat iron bar about 8 feet long, curved so as to be about one foot distant from the axis of the rope in the center where the seat is attached. This is an iron bracket, which, in a wide shafting, is placed on the outer or convex side, while in narrow ones it is inside, in order that the operator may reach the pit-guides with his hand. The attachment is made by fish-plates and bolts, the rope being served with spun yarn at the surfaces of contact; and in these cases, where it is necessary to have the seat within the bow, it should be similarly covered above the seat up to the hight of the operator's head, in order to protect him from dropping grease, etc. The measurement is effected by a steel tape 10 meters (32 feet 9 inches) long, which becomes sufficiently straight by its own weight when suspended. Those of greater length have not been found so convenient.

The method of measurement is very simple: One of the two men, B, on the roof of the cage, works a signal line, which is unrolled from a reel on the surface; the man on the chair, C, then applies the ring of the tape, falling to a fixed point on one of the guides. The second man, A, on the cage, then marks the lower end with a fine cut with a penknife, and numbers it with chalk, 10. B then signals the engine-man, who lowers until ten meters are reeled off the line, when the signal is given to stop. C applies the tape to the 10-meter mark, A marks the 20-meter level, and so on. The above method applies to the wooden guides; where they are of iron, the marks are made with a fine three-cornered file; and when of wire rope, by wrapping a fine wire or thread around them. By this method, the engine-shaft at Leopoldshall salt mine was, when the preliminary preparations had been made, measured three times in six hours, with the following results:

First measurement	334·757 meters.
Second "	334·758 "
Third "	334·758 "

In addition to measuring the depth of the shaft, the positions of eight levels, at different hights, were determined by the same operation.

At the Von der Heydt shaft, at Stassfürth, with seven working levels, four determinations of the depth were also made in about the same time. The results were:

First measurement	353·715 meters.
Second "	353·713 "
Third "	353·717 "
Fourth "	353·714 "

THE NEW TIME STANDARDS.

The proposed new standards of time for the railroads of the country, which are to be established by the General Time Convention of Railroad Managers, has received the approval of the Harvard Observatory, and its co-operation is promised. The railroads centering here acquiesced in the plan on the condition that the time given from the observatory should be correspondingly changed. The consent of Prof. E. C. Pickering, the director of the observatory, being necessary, he was met in New York promptly on his arrival from Europe by Mr. J. Rayner Edmonds, of the observatory, and his hearty approval of the scheme was readily given. Accordingly, a note has been sent to the Secretary of the Chicago Convention, W. F. Allen, to this effect, and assurance given that, if the convention adopts the system, the observatory will be ready to furnish telegraphic signals conforming to the minute and second of the proposed standards.

Under the new system, instead of running the various systems and divisions of systems by as many local standards of time, the continent is to be divided into five broad belts, running north and south, the time for each of which will be one hour slower than that of the next division to the eastward and one hour faster than that of the next division westward. By this plan, the minute-hand of a traveler's watch will not have to be changed, however far he may have to travel or in what direction; but his watch will be just one hour slow when he crosses the imaginary line into the next division to the east, or an hour fast when he crosses the line into the next division to the west. The time now furnished by the Harvard Observatory is the mean solar time for the Boston State House. The new time will be 15 minutes 44·5 seconds—practically 15¾ minutes—slower, and will be the average time for this division, which includes the New England States, New York and Pennsylvania, and the greater part of Canada. North of Lake Erie, the division extends west to Detroit, while south of Lake Erie, Pittsburg is practically on the western boundary of this division. Thus, in the region north of the lake, the standard time will be five hours slow by Greenwich; and south of Lake Erie and west of Pittsburg, it will be six hours slow by Greenwich. The new standard, if adopted, will go into effect on a Sunday noon, and from that hour all the railroads will be run by the new time.

The new time standard was adopted October 11th by 78,000 miles of railroad.

FURNACE, MILL AND FACTORY.

The contract for copper work in the Custom-House at Kansas City, Mo., has been awarded to the Ansonia Brass and Copper Works, of New York.

The Bangor Furnace Company, Bangor, Mich., made a voluntary assignment October 18th. Charles D. Rhodes, of Chicago, president, also made an assignment. He states his liabilities as $130,000; assets, nominally twice this amount.

A dispatch from Cleveland, O., states that some excitement was caused in business circles by the failure of John N. Glidden, secretary of the Republic Iron Company. His failure is said to be solely due to the shrinkage of values in the legitimate iron business. His indebtedness to the company is for ore purchased on his own account and sold to other persons, and for transportation. He also says that in a year and a half he has lost more than $800,000 from this cause. Mr. Glidden's embarrassment will not affect the Republic Iron Company. Its capital stock is $2,500,000, and it is the owner of valuable mining property.

But one blast-furnace in Brier Hill, O., is in operation.

The Falcon and Phœnix furnaces of Brown, Bonnell & Co., are in blast.

The blast-furnace recently started up at Fond du Lac is working with satisfactory results.

The affairs of the Union Iron Company, of Portsmouth, O., have been put into the hands of trustees. The liabilities are estimated at $500,000, and the assets at much less. John Campbell, of Ironton, O., one of the heaviest creditors, has made an assignment to H. S. Neal. These embarrassments affect eight or nine of the largest furnaces in Southern Ohio. Mr. Campbell claims that he can pull through unless his creditors force a sale, in which case he says they will not get more than fifty per cent. It is understood that he holds $150,000 of the stock of the Union Iron Company, and has indorsed its paper to the extent of $200,000.

Randolph Brandt, manufacturer of the Selden patent packing, filled the order for packing the expansion-joints on two miles of 24-inch pipe for the Hydraulic Power Company, at Iron Mountain, Mo. Houses like Edward P. Allis & Co., of Milwaukee, the Knowles Steam-Pump Works, and many of the largest mining and milling companies use this packing on engine and pump-rods.

The Illinois Central Iron and Coal Mining Company has placed an additional order with the Lechner Manufacturing Company, Columbus, O., for chain-elevators for elevating coal at its mines at St. John's, Ill. This company has also received orders for chain-elevators and roller chain belting from the Nelsonville Coal and Coke Company, for its mines at Buchtel, O.

The new works of the Marchand Manufacturing Company, at Pittsburg, are now in operation, and are turning out about 40 per day of their rotary self-measuring pumps.

H. R. Worthington, through his Western agency, is putting in place for the Chamberlain (Dakota) Water-Works a half-million compound pack plunger-pump, and also for the Sandwich Water-Works, Sandwich, Ill., a pump having a capacity of 1,000,000 gallons in twenty-four hours. This house has also furnished a two-and-a-half million compound pumping-engine to the Kankakee Insane Asylum.

The Morgan Engineering Company, of Alliance, O., shipped the other day to the Motala Steel-Works, Sweden, one of the leading establishments in that country, a complete open-hearth hydraulic steel plant, including Wellman's patent hydraulic cranes, stock-hoists, accumulator, Critchlow's valves, etc. This company has also recently shipped one of its 1250 pound single-stand steam-hammers to Vera Cruz, Mexico.

A 60-inch by 16-foot tubular steam-boiler has just been furnished to the Cheyenne Electric Light Company, at Cheyenne, Wyoming, by Fraser & Chalmers, who are now busy on eight Frue vanners and other machinery for the Sierra Valley Mining Company, at Lake Valley, New Mexico. This firm has also just built three Frue vanners for Elling & Morris, Virginia City, Montana, and eight additional vanners for the Germania Company, of Colorado, making eighteen built for that company. Orders for two more vanners have just been booked for the Bullion Cañon Mining Company, of Utah.

The Baugh Steam Forge Co., Detroit, is running its bar, guide, and puddle-mills single turn, and its axle department night and day, with an output of one hundred axles per diem. This company makes a specialty of car-links and pins. At a recent test, its D standard links were found to bear the extraordinary strain of 164,300 pounds, and its 1⅛-inch square links stood 139,500 pounds.

The Allentown *Chronicle* says: The new water-jacket furnace in Reading, Pa., owned by Henry S. Eckert, has now been in blast about one week, and up to this time the result has been very satisfactory; thirty tons of iron are made daily, but it can be increased to forty. This is the only furnace of the kind in the United States. It was designed and built by David Campbell, the superintendent of the furnaces. The jacket surrounds the furnace to the height of 19 feet 9 inches. It is made in sections, so that if an accident should occur to either section, it could be replaced. Between the outer and inner plates of the upper section, is a thickness of five inches of water, and in the lower section four inches. The fresh water is constantly running in above, and is allowed to flow off below through pipes. The experiment is watched with great interest by furnace-men throughout the country.

The Joliet Steel Company, Joliet, Ill., is rolling rails without heating the ingots in the bloom-mill furnaces. Two hundred and fifty rails were recently put at once through the rolls and finished without losing a rail or sending back a single bloom. It is said that the rails worked just as well and as easily as they do when reheated. The soaking-pit process is also to be adopted. This will do away with both rail-mill and bloom-mill furnaces.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY—TOMBSTONE DISTRICT.

GIRARD.—Work on the 200, 300, and 350-feet levels continues. The ore in the latter has completely changed from a sulphuret to a carbonate. Shipments of high-grade carbonate ores to Benson have begun. In the upper levels, the ore is rather low grade, not rich enough to bear shipment, but sufficiently valuable to secure a handsome profit if treated at one of the local smelters. As soon as the Woronoco smelter starts up again, work on those levels will be commenced.

PEDRO CONSOLIDATED.—The tunnel on these properties is in a distance of 470 feet, and, in order to strike the ledge met with in the shaft sunk on the hillside, it is thought that a farther distance of 40 feet will have to be made. The breast of tunnel shows a streak of good ore, and in its course several streaks have been met with, the assays proving them to contain $16, $28, and $33 per ton in silver.

RANDOLPH.—Work has been resumed.

TOMBSTONE MILL AND MINING COMPANY.—It is officially reported that the company has just reached the 5th level in the West Side mine, where the ore runs about 70 ounces silver per ton and carries more lead than the ore in the upper levels. The 3d and 4th levels are supplying most of the ore from the mine, and a discovery in the former gives assays of 820 and 848 ounces per ton. The company has also received telegraphic advices of a rich strike of which no particulars have yet been received by letter.

VIZINA.—A new and very important strike is reported.

YAVAPAI COUNTY.

BLACK WARRIOR.—This mine continues to yield a steady output of ore sufficient to keep the company's mill supplied. The mill is making an exceptionally good record this month. The first week of the month, the ore milled averaged 117·4 ounces, and the chlorinations 92·6 per cent; and the second week, 121·75 ounces, and 91·4 per cent. The company's October bullion product promises to be the largest for any month in its history. Development-work is prosecuted on the company's Tuscumbia mine. Supplies are storing with the view of running the mill during the winter.

CALIFORNIA.

INYO COUNTY—SWANSEA DISTRICT.

INDIANA.—It is stated that ten tons of silver ore from this mine were recently sold in San Francisco for $3200 net. The ore will go to Europe for reduction.

MONO COUNTY—BODIE DISTRICT.

Since the pumping at the Lent shaft has ceased, the water, says the Bodie *Free Press*, has filled the drift at the 1000-foot level and risen pretty nearly up to the 800-foot level. October 12th, it began to show its strength in the 1200 of the Standard. The Standard pump was unable to handle it, and the next morning the level filled up and the miners were driven out. It was not at first thought that the stopping of the Lent would be felt so quickly. It is to be hoped that some arrangement will be made between the two companies whereby work may be resumed in the lower levels of both mines.

STANDARD CONSOLIDATED.—At the request of many Standard stockholders, the superintendent of the company has made a report, dated October 5th, of the present condition of the mine, prospects, etc., from which the following items are taken: East cross-cut, 1200 level, which is 575 feet long, is in soft rock, an indication that the veins may soon be cut which are on the 1000 level, where they show good ore in spots, but are broken and irregular. On the 1000 level, prospecting-work has been steadily pushed ahead. There is quite an improvement in the character of the ore which is taken from uprise No. 2 in south drift No. 2. North drift, on the Fortuna vein, is in 200 feet, and shows the vein 18 inches wide; average assay, $52. The vein, however, is very much broken. On the 700 level, the main north drift, in 375 feet from east cross-cut, shows the vein about 100 feet wide, broken and mixed with clay, and at present low grade. It is improving as it is driven northward, and it is believed will make a large body of milling ore. On the 500 level, the main north drift is in 600 feet. This drift is on the foot-wall vein, which is eight feet wide; then there are about 12 feet of horse matter, beyond which the vein carries about 15 feet of good milling ore, running from $15 to $40 per ton. This portion of the mine is opening out well, and assures an immense quantity of ore for a long time. The level looks well throughout its entire length, and the milling ore gives every promise of extending to the north drift, 700 level. On the 385 level, the ore-body continues to look well, and there is yet a great deal of ore, both in the north and south stopes, running from 20 feet wide in the north to eight feet wide in the south end of the mine. The machinery at the mine is in first-class order. The new 20 by 36 Corliss engine is in place in the Standard mill, and both mills are in good repair.

PLUMAS COUNTY—GREENVILLE DISTRICT.

GARFIELD.—This mine now is under the complete control of W. J. Reynolds. Men have been put to work to get the mine in complete working order.

GOLD STRIPE.—All outside work is suspended for the present. Six miners will be kept at work all winter prospecting.

GREEN MOUNTAIN.—The boiler has been moved from the Cherokee mine to Green Mountain, in order to furnish power for the air-compressor, should the water in the reservoir be exhausted. This will insure the continuance of work in the main tunnel in any event, and, when the new supply of water comes, in all probability the drift will be in or very near the Blake chimney.

SIERRA COUNTY.

ALASKA.—The hoisting and pumping-works building to replace those destroyed by fire several months ago will be completed shortly. The shaft had reached a depth of 457 feet when the fire occurred. As soon as the water is pumped out, the extraction and milling of ore and running of new drills will begin.

COLORADO.

CLEAR CREEK COUNTY.

GENEVA MINING AND SMELTING COMPANY.—These properties have been sold to Judge Wilschire and Major Lanigan, of Arkansas, and General Semmes, of New Orleans. The mine has not been worked for a year. The developments made consist of 2783 feet of tunnels, 3351 feet of drifts and levels, and 1120 feet of shafts sunk upon veins. There is about $500,000 worth of ore in sight and 300 tons on the dump. The Britannic, now in 1050 feet, will be driven 300 feet ahead through the mountain to the Pacific slope near Decatur.

HUKILL.—At a sheriff's sale held in Georgetown, October 16th, the Hukill, Whale, and other mining properties, together with all of the real estate, build-

Digitized by Google

ings, and other property belonging to this company were sold to Mr. George E. McClelland, of Idaho Springs, who has resold the entire property to Mr. J. W. Mackey on private terms. This sale is one of great importance to Idaho Springs. It is said that large ore-bodies lie in the under-working of the Hukill mine. The mine will be put in working order at once.

DOLORES COUNTY.

GRAND VIEW.—The smelter has probably been started by this time. About 250 tons of ore had accumulated from the mines of the Grand View group, the Little Maggie, Butler, Silver Belle, Hope, Cross, South Park, and Clyde mines.

RICO REDUCTION COMPANY.—The capacity of the mill will be enlarged. The operations this season were somewhat restricted by experimental workings with some of Rico's most refractory ores.

LAKE COUNTY.

The Leadville *Herald* gives the following notes about the smelters: The roasting-kilns at the Harrison smelter are in operation and working very satisfactorily. The establishment is receiving considerable desirable smelting ore, and will be prepared to blow in about the first of next month.

The ore supply at Cummings & Finn's smelter is rapidly diminishing, preparatory to transferring the works to the Omaha & Grant Smelting and Refining Company.

The premises of the Arkansas Valley sampling-mill contain about three thousand tons of ore.

The Elgin works, operated by the Manville Smelting Company, are proving quite a success. The company is rapidly accumulating ore, and has now on hand nearly three thousand tons of ore. The preparations for erecting a third furnace are advancing.

The Omaha & Grant Smelting and Refining Company has about 10,000 tons of ore stacked on its premises along the Rio Grande Railroad, in California Gulch.

The work of overhauling and remodeling the La Plata Smelting-Works is making fair progress. The receipts of ores at this smelter are still small, and the establishment up to the present time has not accumulated over 3000 tons of ore. There is little doubt, however, that by the time the La Plata is ready to resume smelting, which will be November 5th to 15th, it will have enough ore on hand, and reliable contracts assure its beginning a campaign with the assurance of maintaining it.

The American Smelting-Works are running along very quietly, and are evidently doing well. The company has from 15,000 to 20,000 tons of ore on hand, costing in the neighborhood of half a million dollars. All the furnaces of the establishment are in blast.

At the Arkansas Valley works, five large furnaces are in blast, and they are expected to smelt 6500 tons of ore this month. The yards and ore-bins contain about eight thousand tons of ore.

ADAMS.—The Clontarf mine, on Carbonate Hill, is pursuing work actively, but producing only a limited amount of ore. The drift designed to connect the Clontarf shaft with the Brookland has about 200 feet still to advance to effect a connection. The Clontarf workings are entirely free from water. In the Brookland shaft, there are about 18 feet of water, which will be cleared shortly. The work of placing pumps in the Wolf Tone shaft is progressing satisfactorily.

ANTIOCH MILL.—Mr. Fruby, who is making practical tests with a concentrating machine at this mill, reports meeting with excellent success in the treatment of Leadville ores. He states that a lot of 18-ounce ore from the Lowland Chief mine has been concentrated, the headings returning a value of $310 per ton. A test on 14-ounce ore from the Venture resulted in concentrates containing 138 ounces in silver to the ton.

BOREEL.—The Gonebrod mine, the property of this company, is now worked. The present resources of the property are confined to large bodies of iron ore, from which regular shipments are made. The probability of opening new ore-bodies are fair.

CHRYSOLITE.—The annual report shows that the mine shipped during the year ended October 1st last, 8055 tons, 1618 pounds of ore, yielding 213,711 ounces of silver and 1,421,050 pounds of lead. From this ore, they have obtained from the smelters $191,974.13. The amount of work done during the past year amounts to 6620 feet of drifts, 993 feet of winzes and rises, and 108 feet of shafting; making a total of 7720 linear feet of underground work. The total amount of workings amounts to 49,347 feet, or, say, nine miles.

EVENING STAR.—The mine is shipping from 35 to 40 tons of ore a day. Included in the shipments is considerable ore ranging in value from 150 to 200 ounces to the ton. The resources of the mine are still quite large. The company has about $86,000 in its treasury, and the expensive new pumping plant for the upper shaft is paid for. The work of enlarging and retimbering the upper shaft has just been completed. Operations on this shaft have advanced very rapidly, and within the next thirty days the pumps will be in working order, and the sinking of the shaft again in progress.

GOLD CROWN MILLING AND MINING COMPANY.—On this property, situated on the Bird's Eye Gulch slope of Mosquito Range, just below the Little Corinne mine, the vein shows a crevice from two inches to three feet in width, filled with pay-rock, from which assays have been obtained running as high as four and three quarter ounces in gold to the ton. Up to the present time, eighty tons of ore have been extracted, returning on an average sixty one dollars per ton. The developments of the mine consist of two tunnels, each sixty feet in length, and an open cut fifteen feet deep. The property of the company consists of a location and an extension on the gold vein, eighty acres of placer ground, and a five-acre mill-site.

LITTLE PITTSBURG.—The properties are doing fairly well. The bins at No. 9 shaft show some very fine ore, including specimens covered with native silver; but its appearance indicates that it is the product of seams and pockets. A boiler is getting into position on No. 10 shaft, and the task of straightening the shaft and preparing it for work will be commenced soon.

MAY QUEEN AND MOYAMENSING.—The controversy between these two claims remains unsettled. Both sides are still producing ore, and the May Queen is reported shipping large quantities of ore ranging in value from $60 to $120 per ton. The Moyamensing is also shipping considerable ore, but of inferior grade.

MORNING STAR.—An average of eighty-five tons of ore a day is shipped. The workings of the mine throughout are looking well, and ore is disclosed to view in a score of different points through the mine. The Waterloo, McHarland, and the old main shafts are all producing largely.

PARK COUNTY.

NESTOR.—The property is now actively developing. The consolidation embraces a mill-site and eight locations, as follows: The Winchester, Montgomery, Robert Keeley, Gold Leaf, Silver Leaf, Illinois, Ensign, and Blue Grass, covering a strong vein for a distance of 2500 feet. Twelve openings have been made on the vein, ranging in depth from 15 to 130 feet. These developments show the vein to have a northeast course, with a dip to the southeast of about sixty degrees from the horizon. The average width of the fissure is from six to seven feet. Sample assays gave returns as follows: At a depth of thirty feet from the surface, one half-ounce of gold, thirteen ounces of silver, and sixty per cent of lead. At the surface, one half-ounce of gold, fifteen per cent of lead, and eight ounces of silver. At 120 feet, the mineral is a clear sulphide, consisting of galena, iron and copper pyrites, free gold, and sulphide of silver, possessing an average value of $60 per ton. The gangue rock accompanying the vein at this depth also shows a profitable value, returning $25 per ton without sorting. The main shaft is located on the Keeley claim, and has a depth of 130 feet, with cross-cuts to the vein at 25, 65, and 120 feet from the surface. The vein can be traced for several thousand feet, and is unquestionably the principal vein in this section of the country. Parallel to the vein, about 300 feet to the eastward, is a second vein, generally known as the Susquehanna vein. It is opened by an adit showing a width of from four to five feet of a promising nature. The lead is also developed in the Susquehanna lode, an adjoining property, and demonstrated to possess great value. There are now about 1000 tons of ore in bins and on the dumps, from which a lot of eleven tons was selected and shipped without sorting, returning $23.55 per ton in silver and gold, no account being taken of the lead and copper. There are also about 6000 tons in sight in the mine, ready for extraction.

SOVEREIGN.—Buildings are now going up to aid in continuing work through the entire winter. The result from the late mill-run has been very satisfactory.

PITKIN COUNTY.

A correspondent of the Denver *Tribune*, speaking of the mines around Ashcroft, says that the character of the mineral is principally galena, gray copper, and silver glance, in quantities sufficient to justify steady developments. The lack of capital in the county has thrown quite a number of valuable properties on the market at exceedingly reasonable figures, and several sales are now making. Among the most promising mines in the district that are now worked, with mineral awaiting the whistle of a smelter, are the Minneapolis, Congdon, Leona, Osburne, Cummings, Boulder City, Keno, Eureka, of the Paradox group, Pearl, Highland Chief, Wichita, Gray Eagle, Yellow Boy, Michigan, Rainstorm, Dauntless, and many others.

Several good strikes were recently made fifteen miles east of Ashcroft, the most important being the New York. A mill-run of 1900 pounds lately shipped to Leadville gave a return of 793 ounces of silver to the ton. The ore is chloride and native silver.

SAN JUAN COUNTY.

A correspondent of the Denver *Republican* reports on the various mining districts as follows:

RED MOUNTAIN DISTRICT.

The Yankee Girl has shipped over 4000 tons in the past ten months. The National Belle is shipping about twenty-five tons per day, averaging $80. These ores go to Denver via Silverton. But the low transportation offered by the Mears system of roads and iron rail tramways—$7 per ton laid down at Montrose—will bring the ores through Ouray for the Denver market. It will be a saving of about 50 per cent. In the same district, are also Orphan Boy, Robinson, Genesee, Champion, and Guston—known as the Yankee Girl Group—all shipping ores. Guston is shipping ten tons per day, this averaging $70. Within this district, are the American Girl, Congress, Senate, Humboldt, Ivanistan, Bobtail, Comet, Great West, and McIntyre mines; also, the celebrated Jed mine, the Pennsylvania, the Carbonate King, Sailor Boy, and Carbonate Queen properties; the Saratoga, Albany, Maud S., Belle of the West, Brooklyn, Bonanza King, H. A. W. Tabor, the Guadalupe & Black Raven, the Galena Lion, Mountain King, and Sunshine. Some of these mines ship fron 5 to 10 tons per day, averaging from $55 to $75. Many are undergoing development and have large quantities of ore on the dumps awaiting shipment.

SAN MIGUEL DISTRICT.

On the other side of the mountain, from Virginius Basin, are the Sheridan, Smuggler, Mendota, Union, and Cimarron. The ore of these mines contains native and brittle silver, galena and gray copper, and are of a high grade, and carry some gold. They have been shipping all the season by way of Telluride and Ouray to the Denver & Rio Grande at Montrose; but as soon as the Mears roads reach over into Marshall Basin from Red Mountain, these mines, together with all the producing mines in the basin, such as Argentine, Hidden Treasure, Cincinnati, Baby Elephant, Alamo, and many others, will take this shorter route and lower rate of transportation and ship to Ouray exclusively, where concentrating and reduction-works will most likely be built next season by Senator N. H. Hill.

SNEFFELS DISTRICT.

In Imogene Basin, are the Yellow Rose, Agnes, Declaration, Hidden Treasure, Hancock, and Imogene. These have high-grade gray copper, with galena, and run well in silver and to a considerable extent carry gold.

On Ruby Mountain, are the Wheel of Fortune, Potosi, Revenue group, Stonewall Jackson, Neptune, and Highland Chief. These show high-grade gray copper, galena, brittle silver, and some gold.

In Cumberland Basin, are the Cumberland, Nashville, Banker, Atlas, Sidney, and Monarch, carrying mostly galena.

In Virginius Basin, are the Terrible, Tornado, Bank of San Juan, Virginius, Monongahela, Blue Grass, Raleigh, Shamrock, and Spotted Tail. These exhibit galena and gray copper, with native and ruby silver. The mills-runs from some of their claims are as high as 500 ounces of silver to the ton and 43 per cent lead. In the Virginius, the ore is galena and gray copper. It has sold $75,000 worth of ore.

UNCOMPAHGRE DISTRICT.

About four miles from Ouray, up the Uncompahgre, are the Silver Link, Climax, Epoch, Tidal Wave, and Silver Star. These mines are in a continuous ore-body, from which mill-runs have given 160 ounces of silver and 20 per cent of copper per ton.

Near Mineral, at the terminus of the Mears road to that place, are the Challenge, Confidence, Friend, Grand Junction, and Crystal. These mines run well in silver, with little copper, and carry some gold.

In Poughkeepsie, and on that branch of the road, are the Royal Albert, Alaska, Mickey Breene, Flag-Staff, and Grand Era. These ore-bodies show large quantities of gray copper, and run well in silver.

On Bear Creek, about three miles from Ouray, are the Belle of Ouray, Bismuth, Toledo, Black Bird, Black Prince, Leviathan, Union, and Monitor, carrying large quantities of gray copper and brittle silver.

SUMMIT COUNTY.

ROBINSON.—Mr. Greer, the lessee, is reported as meeting with poor results in the development of new ore-bodies in the lower levels. The ore in the face of the lower incline has deteriorated in grade, until it will no longer pay for extraction and treatment. From other portions of the mine below the tenth level, Mr. Greer succeeds in extracting almost a car-load of ore a day. The sub-leasers on the property are said to be doing well. Mr. Horten, who has the upper levels, shipped ten car-loads of ore during September, amounting to about ninety-five tons, which averaged over seventy-five dollars to the ton. A car-load from the same lease is now at one of the Leadville works, and the output from this source will aggregate from six to eight cars this month, of fair ore. Sub-leasers on other portions of the mine and on the dumps are also reported doing well, and obtaining considerable ore of fair grade.

DAKOTA.

FATHER DE SMET.—The superintendent reports, October 8th: Golden Gate south header still keeps in ore and is showing as well as usual. Where we are breasting across, the ore looks well and seems to be quite extensive. East cross-cut, third level, has gone into ledge-matter, which, I think, must belong to the Golden Gate ledge; but as yet, it is mixed up considerably with slate and samples low. The rest of mine does not show up quite so well this week, as we have been compelled to break down a lot of very low-grade ore, but shall pull up again next week. The mill is running well, and every thing is going ahead in full blast. The report for the week ended October 14th shows: Ore extracted from first level, 900 tons; second level, 800 tons; third level, 400 tons. Ore milled, 2100 tons. Golden Gate cross-cut, third level, advanced five feet. Golden Gate south header, second level, advanced seven feet.

HOMESTAKE.—According to the Deadwood *Times*, the Giant & Old Abe mine,

Digitized by Google

at Lead City, the property of this company, has the finest and most expensive hoisting and pumping machinery east of the Rocky Mountains. It was completed two years ago, at an expense of $150,000, and since that time has been almost idle. The machinery is so complete and perfect that it can be put down 2500 feet without any additional machinery. The shaft is down 444 feet, the deepest one in the Hills, and it is all the way in ore, or nearly so, and there has been none milled from this mine except what came from the shaft, and a small portion on the 100-foot level of the Homestake mine. The superintendent will soon put on a force of men, day and night shift, and sink the shaft 200 feet deeper, regardless of what may be encountered. The shaft is a three-compartment.

IDAHO.

PHILADELPHIA.—The two new fifty-ton furnaces of this smelting company at Ketchum are running regularly, and turning out between 30 and 50 tons of bullion per day. These furnaces will continue to work until January, when one stack only will be operated during the rest of the winter.

SILVER KING.—The parties who held a working bond on this mine, situated in Beaver Gulch, about three miles above Sawtooth, have purchased the same for $125,000. The purchasers are also owners of the Davitt mine on Deer Creek.

VIOLA.—The syndicate which bought this claim on Willow Creek has been pushing work for several months, and is shipping ore at the rate of 600 tons per month. This ore, averaging forty-five per cent lead and forty ounces silver, is hauled to Camas station on the Utah & Northern, and thence shipped to Kansas City. Some has been shipped to Salt Lake City, and has been smelted at the Hanauer smelter. The success of this property will have the effect of opening up others in that district. There are over 30,000 tons of ore in sight.

MAINE.

PORTLAND SMELTING-WORKS.—The company has purchased of Messrs. Jones and others the right to use their patent vapor fuel process, and will adapt the works to said process, under the personal superintendence of Mr. Jones, who guarantees the smelting of all ores at less than one third of the present cost for fuel, thereby making it possible to smelt exceedingly low-grade ores at a profit.

STEWART.—Recent developments are reported to be of a most interesting character. In the bottom of No. 3 shaft, at the depth of nearly 300 feet and in the copper-bearing rock, the workmen have come upon a vein of quartz heavily charged, as it appears, with antimonial sulphuret of silver. Apart from this recent discovery, says the Bangor *Journal*, the outlook at the mine is encouraging, so far as the character of the ground and progress of the work are concerned. The southern cross-cut is reported to be in fair copper, and the vein in the northern cross-cut is rapidly improving. The latter has reached a distance of some eighty feet from the shaft, being considerably more than half-way to the open cut which it was started to reach.

MEXICO.

The San Rafael, near Zacatecas, is continuing to pay dividends at the rate of $75,000 per month.

The Cinco Señores Company is erecting the first stamp-mill in the State of Zacatecas, with a capacity of from 25 to 30 tons per day. It will treat as much ore as the present hacienda, which employs 600 animals and has cost $200,000, while the new mill requires only an outlay of $50,000.

MICHIGAN.

CALUMET & HECLA.—"Superior," the monster engine of this company, was recently started up, making as high as fifty-five revolutions per minute. Connection has been made with the air-compressors.

CENTENNIAL.—Work has been suspended for lack of funds. The Houghton *Mining Gazette* states that the late Jesse Hoyt, of New York, was a large owner in the mine, and his executors do not see their way clear to advance any more money, while the other owners are not disposed to continue work under the circumstances. The discontinuance of operations at this time was unfortunate, for the reason that the Osceola lode, which was worked, was developing copper ground equal to the average taken from this deposit.

HOUGHTON.—An assessment of one dollar and a half has been levied, for the purpose of sinking shafts and extending levels.

LAKE ANGELINE.—The exploration of the diamond drill on the ground west of the old mine workings has showed such good results that a shaft has been sunk, and numerous other developments made. About 11,000 tons have been raised since hoisting began two months ago, and this was all taken from the drifts and cross-cuts of preparatory nature. In quality, the mineral stands at the head of the hematite mines of the region. An assay lately made shows 68·30 in metallic iron and ·024 in phosphorus.

STANLEY IRON MINING COMPANY.—This company, which has been exploring the east half of section 26, 40-30 has suspended all work there for the present. At three different places on the property, an attempt was made to get the ledge with a churn-drill, which resulted in failure. A test-shaft was sunk some 30 feet, but so many boulders were met with that the work of sinking was exceedingly slow and expensive. The property is looked upon as a most promising one by old explorers, and work upon it will undoubtedly be resumed in a short time.

ST. LAWRENCE.—The mine has been closed down. This was done on account of the condition of the market and the low grade of the ore. It is probable that mining operations will be resumed the coming spring; and in the mean time, some exploring will be done in hopes of finding ore of better quality.

STURGEON RIVER IRON COMPANY.—All operations have been discontinued on section 7, town 39, range 28.

MONTANA.

SILVER BOW COUNTY.

Some recent reports state that a 100-ton custom smelter will be located in Butte by a syndicate of Eastern capitalists.

MONTANA COPPER COMPANY.—The work done at the Calusa mine is reviewed as follows: The shaft is now down 400 feet. Several thousand feet of levels have been run. The ore product is about 100 tons daily, and could be doubled for an indefinite period simply by increasing the working force. Five matting-furnaces and one blast-furnace are in constant and successful operation. The company is shipping an average of 20 tons of matte every day, as well as a large amount of crude ore from Colusa and Liquidator (the latter on contract), the total daily shipments being about fifteen car-loads, or in the neighborhood of 75 tons.

MOUNTAIN VIEW.—The work of development has steadily progressed, and the shaft, a vertical one, has been sunk to a depth of 514 feet. At a depth of 300 feet, a cross-cut was driven south from the station for a distance of 200 feet. This cross-cut, at a distance of 150 feet from the shaft, tapped the foot-wall of the vein, which has been penetrated for 50 feet without, as yet, encountering the hanging-wall. Throughout the enormous width of the ledge, so far as explored by this cross-cut, bunches and streaks of copper ore constantly occur, as they did above the main copper deposits in the St. Lawrence and Anaconda, leaving very little doubt that at an increased depth the entire space between the widely separated walls will be filled with pay-ore identical both in quality and amount with that of the above-named properties. At the 400-foot station, a cross-cut south has penetrated the country-rock for a distance of 75 feet, but the ledge has not yet been encountered. Driving south vigorously progresses. At a depth of 500 feet, two cross-cuts have just been started, one to tap the main ledge on the south, the other to intersect a vein which crops on the surface north of the shaft.

NEVADA.

EUREKA COUNTY.

EUREKA CONSOLIDATED.—At the annual meeting of the stockholders, held in San Francisco recently, the following Board of Directors was elected for the ensuing year: Solomon Heydenfeldt, Charles Simpkins, Captain Knowles, A. McKenzie, and J. McKenzie. The three first-named gentlemen are from California, and the two latter from New York. The Board of Directors met and elected T. J. Read Superintendent, and P. Jacobus Secretary. Reports from the mine show that the furnace is running, and that the water in the Locan shaft was reduced, October 16th, to within 30 feet of the station at the bottom, and the indications are, that the flood has been overcome. At the present rate of pumping, the bottom will soon be reached. It seems as though the underground reservoirs from which the flood came had been pumped pretty nearly dry.

EUREKA TUNNEL.—Several stockholders dissatisfied with the management recently held a meeting. A committee was appointed to investigate the affairs of the company.

LYON COUNTY.

The old French mill, the last mill but one remaining intact in Silver City, is, says the Virginia City *Chronicle*, to be dismantled. The work has begun. One by one, all the quartz mills that used to be in Gold Cañon have disappeared. Silver City, which once was a hive of mills, now contains but one, the old Sherman mill, a small concern.

STOREY COUNTY.

ALTA.—Excellent headway is making in draining this mine, and the time is not far distant when the miners will again be at work in the lower levels.

BELCHER & CROWN POINT.—It is expected that the mines will start up with a full force shortly. At the Crown Point, about eighty men are employed.

NORCROSS.—There are rumors of an improvement on the 2700 level.

SUTRO TUNNEL.—The report for the week ended October 8th shows that the following temperatures were observed:

	Air.
Tunnel entrance, water 118	58
Shaft, No. 1 east	79
" " 1 west	80
" " 2 east	90
" " 2 west	55

Flow of water in standard gallons per twenty-four hours, 8,852,600.

WHITE PINE COUNTY.

A San Francisco company has been engaged for some time in erecting a mill for the purpose of working the ores of the Linton and Monroe mines. The mill is located at Cabin Springs, and an abundance of water and timber can be had to supply it. The ore runs $80 in gold, and a large amount of it is already out awaiting the completion of the mill, which it is thought will be ready to drop stamps about the 20th of December. This district is tributary to Salt Lake, and during the placer excitement, years ago, a market was found for the gold in that city by the placer miners. At present, but little is doing in the placer mines, but the ground is rich, and when appliances are secured for working them, they will start up again.

NEW MEXICO.

LINCOLN COUNTY.

HARDSCRABBLE.—The present owners have purchased a large amount of machinery, among which is a stamp-mill which will be erected soon.

SAN ANDRES.—Assays and mill-runs recently made of copper ores from this mine justify the erection of a smelter.

SOCORRO COUNTY.

The report has often been circulated, says the Socorro *Sun*, that we are destitute of iron ore in this vicinity. This is a fallacy which should be corrected, and the statement is usually made by parties who are envious of our prosperity and innumerable resources. In addition to the vast bodies of ore heretofore discovered, a very extensive body of iron has just been discovered within a few miles of Socorro. The nearness of this latest strike will materially diminish the cost of smelting ores at this point. The new find is situated in the south end of the Socorros.

TEXAS.

HARDEMAN COUNTY.

Denver papers report that ex-Senator Tabor has completed the purchase of the beds of carbonate of copper, lying in this county. The deposits of this ore cover an area of from 160,000 to 170,000 acres, and the purchase price was $250,000. For three years, the matter has been under negotiation, and now a company has been organized and will begin immediately the work of developing the tract. The company is known as the Copper Syndicate, composed of ex-Senator Tabor, of Colorado; Yates Ferguson, Dr. C. R. Bissell, B. F. Dalton and several other capitalists of New York City. The syndicate has put itself into correspondence with the Denver & New Orleans Railroad. The proposed lines of this road run within fifteen miles of these copper ore-beds, and the proposition is that, if the company will extend its line to that place, a shipment of 500 tons of copper per day is assured. A meeting of the directors is to be called to look into the project. It is stated that this assured shipment of 500 tons per day is fully sufficient to pay the company to make the extension. The shipment is to begin six months after the road is completed, and to continue indefinitely.

UTAH.

BOX ELDER COUNTY.

BROOKLYN.—This company, operating the property formerly known as the Martin mine, at Bingham, is working on a body of ore twenty feet wide, on the 900-foot level, and is sending to the smelters nearly 1000 tons of ore per month. The value of this ore has improved with depth.

LEAD.—Good news is reported from this mine at Bingham. All former workings have been in low-grade ore, which required concentrating, and the concentrates were nearly all lead with a small percentage of silver. The foot-wall has been tested, and a car-load of this quartz ore assayed forty ounces silver and only one per cent lead. Hand samples running as high as from 200 to 300 ounces have been tested.

SUMMIT COUNTY.

MINNIE WHEELER.—The shaft has reached a depth of 55 feet, and for over 30 feet the miners have been cutting little veins and seams of ore.

UTAH COUNTY.

SILVER BELL.—This property, consisting of seven patented claims, has been developed by a shaft 385 feet deep, and by a tunnel in 1300 feet. The shaft was sunk from a point high up the mountain, and went through good ore all the way down, but operations from that point were difficult and expensive. To obviate this and at the same time open up the other six claims, a tunnel has been run in a distance of 1300 feet, and a contract has been let to extend this tunnel 1200 feet more. When it is finished, the tunnel heading will be under the shaft, and 1200 feet below the surface, making it one of the deepest mines in Utah. It is proposed then to continue the tunnel 1000 feet farther, in all 2500 feet, cutting clear through the hill. Besides the tunnel contract, another was made to run 400 feet of cross-cuts. So far, $80,000 have been spent on the property. At the foot of the shaft, the vein is 55 feet wide, six feet of which is milling ore running 54 ounces silver. Over 3000 tons of such ore are on the dump.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Oct. 26.

The mining market this week has been very dull and almost featureless. Outside of the fancy stocks, there has been but a very small business. The Comstock shares were a feature of the market on account of their weakness. The Leadville stocks were quiet and steady. Horn-Silver was quite weak to-day, selling as low as $6. We give a full summary of the market below. The total number of shares sold aggregates 136,750, as against 152,376 last week.

The Comstock shares were very quiet, and were inclined to weakness. California sold from 15@12c., assessment paid, and at 9c. assessment unpaid. Consolidated Virginia was quite weak, under a small business; it sold from 54@48c. Sierra Nevada was also weak, selling from $4.50@$3.65@$3.85. Union Consolidated was weak, selling from $4@$3.65. Mexican was moderately dealt at steady prices; it sold from $3@$3.40@$3.30. Best & Belcher sold at $3.90. Sutro Tunnel was quite active, and was a little weak; it sold from 18@16c.

The Leadville stocks were also very quiet, and prices are steady. Amie Consolidated was quiet and steady at 11@12c. Chrysolite records a small business at about steady prices, selling from $1.15@$1.10. Dunkin sold at 26c. Iron Silver was moderately dealt in at steady prices; it sold from $3.95@$3. Leadville sold at 37c. Little Chief was irregular under a small business; it sold from 55@65@57c. Little Pittsburg was quiet and steady at 61 58c. Climax showed a little strength, under moderate business, selling from 8@14 11c.

The Bodie stocks were almost neglected. Bodie Consolidated sold at 55c., and Standard was quiet and steady at $5.88@$6.

The Tuscarora stocks were quiet and steady. Grand Prize was moderately dealt in at 50c. Argenta sold at 20c. Belle Isle was steady, with a small business, selling from 42@47c. Navajo was dealt in to the extent of 100 shares at $3.25. North Belle Isle was a little weak, under a moderate business, selling from 65@60c. Independence sold at 40c. Elko Consolidated was very active at irregular prices; it sold from 3@6@8c.

In the miscellaneous list, Alice was quiet and steady at $2.65. Bassick was a little weak, selling from $10 @$9 under a small business. Eureka Consolidated was quiet and weak, selling from $5@$3.90. Hall-Anderson was moderately dealt in at steady prices, selling from $1.15@$1.10. Horn-Silver was quite weak, with a moderate business, selling from $7 @ $6. Robinson Consolidated was very quiet and was steady, selling from 42@47c. Sierra Grande was also very quiet and steady; it sold from $1.10 @$1.05.

Barcelona was quiet and steady at 28@27c. Bradshaw sold at 21c. Decatur was moderately dealt in at irregular prices, selling from 4@2@3c. Eastern Oregon was very active at steady prices; it sold from 42@45c. Harlem was also very actively dealt in, but it was irregular; it sold from 92@95@91@92c. Lacrosse was quiet and irregular at 8@6@7c. Sonora Consolidated was but moderately dealt in at steady prices; it sold from 23@25c. Castle Creek sold to-day to the extent of 1000 shares at $1@$1.05.

There is considerable grumbling among the stockholders of Alice at the difficulty in getting any reliable data as to the financial condition of the enterprise. Since the suspension of dividends, the mine has been turning out silver at the rate of more than $100,000 per month, which must be very much more than the expenses amount to. The net earnings must have been during that period sufficient to pay the floating debt, the purchased price of the Magna Charta, and the cost of pumps and other improvements.

An official report from the South Yuba Water and Mining Company states that the profits of the company have been expended in improving the property, and that it is expected that the earnings this year will be over $100,000.

The Board of Trustees of the Chrysolite Silver Mining Company has issued the following circular:

In view of a possible delay of several weeks in the preparation of the full annual report, including the statement of the general manager, treasurer's accounts, etc., it is deemed advisable to present a brief general summary of the operations of the last year.

The estimated surplus at the end of September was a little over $200,000; and practically, therefore, the work of the year has resulted in no profit; in other words, a very large amount of prospecting and deadwork has been done and the expenses have been paid out of the proceeds of ore mined. Included in these expenses is a sum of $2500 paid for the outstanding one quarter interest in the Kit Carson and All Right claims, an interest which, since the organization of the company, has been held by outside parties and for which a large sum was formerly demanded. Patents have been obtained for these two claims; and the legal title being now beyond further attack, prospecting is actively going on in this ground.

The prospecting-work of the year, details of which will be given in the annual report, has demonstrated the existence of three layers of iron-bearing material under the upper layer which contains the old workings. In all these layers, the iron has been proved by numerous assays to contain some silver and lead, and constitutes therefore the matrix in which pay-ore may occur. Sundry pockets of ore have been found here and there, but as yet no continuous bodies of profitable grade.

The most important and expensive of these explorations has been made in the second layer by the incline from Colorado Chief shaft No. 2, referred to in the last annual report. The bottom of this incline is still about 200 feet from the Roberts shaft, and therefore from the region in which the largest and richest accumulations of ore in the upper layer wereencountered. This region, it will be remembered, it was attempted to explore by sinking the Roberts shaft. The incline has advanced somewhat slowly, because the work of sinking it has been interrupted from time to time, to permit the exploration by winzes and drifts of the ground through which it was passing. These explorations have yielded in the main only low-grade iron. As will appear more fully in the annual report, the undeveloped ground of the company has been by no means exhaustively tested, and there are several points in which both the indications of our own workings and the results obtained in the neighboring mines permit us still to indulge in reasonable hopes of finding profitable ore-bodies. Meanwhile, the old bodies which have furnished the dividends of former years have proved unexpectedly extensive, although the remaining portion which has been worked during the past year has been of low grade. It is of course impossible to say how long these sources of income will continue; but there is undoubtedly a considerable amount, both of this low-grade ore and of the richer ore scattered here and there through the old workings, which is removed by lessees on terms very favorable to the company.

In addition to these resources, the value of the dumps should be considered. A contract under negotiation by which the iron dumps would have realized without expense to the company a net value of about $100,000 was unfortunately not concluded in time to permit the erection by the contractors of the necessary works during the present season. It is not certain that the same parties will renew their offer next spring; but the careful and extended experiments by which the gross value of the dumps has been accurately determined justify the assurance that such an arrangement can be made on terms satisfactory to both parties, or, on failure thereof, the company can treat its own dumps with a somewhat larger profit. The trustees preferred, on the whole, the proposed contract, because it relieved the company of the expense of erecting works.

It must be admitted that the failure during this year to discover new bodies of pay-ore is to that extent discouraging; but the indications still continue sufficiently favorable to warrant a further prosecution of explorations with energy, and with hope; and for the thorough execution of this work the company possesses ample means.

A visit to the offices of the different Leadville mining companies in this city shows that their present financial condition is better than for some time past, and that in many instances their prospects are brighter for the future. Amie, after paying the dividend just declared, will have a surplus of about $9000 on hand. Reports from the mine state that No. 5 shaft is worked steadily and that good ore has been encountered. The Morning Star Company recently declared a dividend of $25,000, and has a good surplus on hand. The Chrysolite Company has in its treasury between $203,000 and $204,000. The Iron Silver has $100,000 on hand. The product of the mine for September realized $144,016.83. The Little Pittsburg Company has $43,000 on hand. The mine is reported to be in good condition. The Little Chief Company has $50,000 in government bonds and about $10,000 cash available. The reports from the mine are of a very favorable character. The Leadville Company reports a surplus of about $15,000 after paying the dividend recently declared.

MEETINGS.

The Chrysolite Silver Mining Company, No. 18 Wall street, New York City. Annual meeting of stockholders and election of trustees, November 7th, at twelve o'clock M.

The Colorado Central Consolidated Mining Company, No. 25 William street, rear, New York City. Annual meeting of stockholders and election of trustees, November 8th, at eleven o'clock A.M.

The Idaho Consolidated Gold and Silver Mining Company, No. 114 Wall street, New York City. Annual meeting of stockholders and election of trustees, October 31st, at twelve o'clock M.

The Penobscot & Snow-Drift Consolidated Mining Company, office of company, Vestel, Montana. Annual meeting of stockholders and election of trustees. The proposition as to whether or not the company shall be dissolved and disincorporated is also to be discussed; and in case it shall be decided by a vote of two thirds of all of the stockholders to disincorporate and dissolve the corporation; then proceedings will at once be instituted to do so.

DIVIDENDS.

The Calumet & Hecla Copper Mining Company, of Michigan, has declared its regular quarterly dividend of $5 per share, or $500,000, making the total amount paid to date $24,350,000.

The Silver Cord Combination Mining Company, of Colorado, has declared dividend No. 3, of ten cents per share, payable November 1st, 1883, at Room D, No. 305 Walnut street, Philadelphia. Transfer-books close October 27th, and reopen November 2d.

The Morning Star Mining Company, of Colorado, has declared a dividend of $25,000.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway, report that during the past week, until Thursday, extreme dullness prevailed in the petroleum market. The market seemed to have got into a rut, and the trading was so light and fluctuations so small that there was no temptation to the public to speculate. On Thursday, however, the rumor that the monthly report would be bullish, infused new life into the market, and prices rallied under a very active market. The market to-day was very active, but prices ruled weaker and closed unsettled.

The production of Balltown and Cooper tracts, though less than two weeks ago, holds up remarkably well. The shipments from the oil regions to the seaboard exceed the receipts from the wells by about ten thousand barrels daily, which insures a reduction of stocks again this month.

The price of refined oil has remained unchanged during the month at 8½ cents.

Messrs. Watson & Gibson have issued a small pamphlet, giving full information as to the situation on the oil-field, the influences governing the market, statistical facts, etc., which may be had on application.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Oct. 20.....	$1.10	$1.10¼	$1.09¼	$1.10⅛	1,892,000
22.....	1.10⅛	1.10¾	1.09¾	1.09⅞	3,318,000
23.....	1.09⅞	1.09⅞	1.09¼	1.09¼	2,390,000
24.....	1.09	1.09½	1.08⅞	1.09¼	1,886,000
25.	1.09⅛	1.11⅛	1.09½	1.11¼	3,388,000
26.....	1.11½	1.11½	1.10⅛	1.10⅜	3,454,000
Total sales.					16,328,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, October 25.

There has been but little doing in mining shares the past week, and prices show very little change. The market is so dull and inactive that it is difficult to get quotations for the general market, sales being confined principally to a few of the leading copper stocks which are bought for investment, and there is no speculative demand. Calumet & Hecla is firm at $239, but only four shares changed hands the past

Digitized by Google

week. Franklin, on sale of 100 shares, declined from $12 to $11¾. Quincy sold at $50, same as last week. A single share brought $52. Osceola declined from $18½ to $18, but later rallied again to $18½ on small sale. Pewabic declined from $1⅜ to $1¼, at which price all offered was taken; later, assessment ($1) paid, it sold up to $2⅜@$2½.

In silver stocks, the market shows no improvement, either in prices or activity. Bonanza declined from $1¾@$1½, with sales of 700 shares at that figure. Catalpa was steady at 30c. Silver Islet declined from $3 $2. Sullivan advanced from $⅛@$1, with sales at the Mining Exchange at $1.02@$1.05. The reports from the Sullivan are said to be promising, and its friends predict higher prices for the stock in the near future. The stock is largely held by a few individuals, and it is not a stock to sell short to any extent, as it might be difficult to cover at short notice. Bowman Silver and New Mexico seem to have gone to sleep, the transactions being extremely limited and no disposition to operate.

3 P.M.—At the afternoon Board, Calumet & Hecla sold at $239, and bid. Sullivan, $1. Atlantic, $11 bid, $12 asked. Franklin, $11 bid, $11¾ asked. Quincy, $51 bid, $53 asked. Osceola, $18 bid, $18½ asked. Pewabic, $2⅝ bid, $3 asked. Closing prices: Allouez, $1½@$2; Bonanza, $1⅝@$1¾; Silver Islet, $1½@$3.

SAN FRANCISCO MINING STOCK QUOTATIONS.

BULLION MARKET.

NEW YORK, Friday Evening, Oct. 26.

The London market has been weak since our last postings, and sterling exchange has also marked lower figures the past week, affecting our market for silver as per accompanying table. A slight rally in each, is shown in our rates for the day, but the market is uncertain.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
Oct. 20	51	110¾	Oct. 24	50⅞	*
22	51	110¾	25	50⅞	*
23	50⅞	*	26	50 15-16	†

* 110⅝@110½. † 110½@110⅝.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended October 26th, as compiled from various sources, amounted to $153,000, as against $218,000 reported for the previous week. The receipts from January 1st, 1883, to date are $9,316,047.

Foreign Bank Statements.—The governors of the Bank of England, at their weekly meeting, made no change in the bank's minimum rate for discount, and it remains at three per cent. During the week, the bank lost £408,000 bullion, but the proportion of its reserve to liabilities was raised from 43¾ to 43 15-16 per cent, against 36 11-16 per cent at this date, 1882. October 25th, the bank lost £13,000 bullion on balance. The weekly statement of the Bank of France shows losses of 4,050,000 francs gold and 2,275,000 francs silver.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

Purchase of Silver.—The Treasury Department, October 25th, purchased 425,000 ounces of fine silver for delivery at the Philadelphia, New Orleans, and San Francisco mints.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended October 20th	$522,918
Corresponding week last year	59,762
Since January 1st, 1883	12,078,152
Corresponding period last year	44,387,257

Imports.

Week ended October 20th	$628,812
Corresponding week last year	141,371
Since January 1st, 1883	13,542,054
Corresponding period last year	3,945,188

METALS.

NEW YORK, Friday Evening, Oct. 26.

Copper.—As usual, the supplying of manufacturers and dealers by the extension of the former contract to the end of the year has left the market for Lake in a very dull state, only small parcels changing hands at 15⅛c. It is a matter of surprise to many in the trade that the smaller companies allow the Calumet & Hecla to continue to run their business so far as the sale of their product is concerned. As we have reached the export basis, they can have little to fear from any attempt of their big rival to break the market, and it has not now any real power to force them into submission. Many of them would probably be able to do better now by themselves.

In other brands, there is little doing, and while the offerings of furnace material to the refiners are light, the inquiry for this copper is not very large. We quote, 14¼@14¾c., according to brand.

England cables $61 15s. for Chili Bars, and £88 for Best Selected, an improvement over late quotations.

Tin.—The market is very dull, so far as large line are concerned, and futures are freely offered at 20¼c. There is a fair jobbing demand at 20¾c. spot cash for Straits. London cables £94 2s. 6d.

Lead.—The market is very dull and lifeless, nothing but jobbing sales at 4·20c. being reported.

Both Common and Refined are offered at 4·18c. and for future shipment quotations go close to 4c. The lower figures at which bullion is selling have a depressing effect.

Messrs. John Wahl & Co., of St. Louis, send us the following dispatch to-day:

Our market is unchanged, being firm at 3·90c. for Refined, and 3·92½c. for Chemical.

Messrs. Everett & Post, of Chicago, wire to-day:

Our market remains about the same, being if anything a trifle weaker, with prices nominally, at 3·90c. There has been scarcely any fresh business since our last report, and sales do not aggregate more than 300 tons.

Spelter.—The market continues dull and lifeless, with Common and Domestic nominally at 4½c., which, however, could probably be shaded.

Antimony.—This metal is firmer, with Cookson's at 10¼c. and Hallett's at 9⅛c.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Oct. 26.

The following have been the exports from Great Britain to this country during the first nine months of the current year:

	1881.	1882.	1883.
Pig-iron	308,933	384,715	218,994
Old iron for re-manufacture	66,153	71,445	39,340
Steel unwrought	87,446	118,141	25,364
Tin plates	129,586	164.249	162,934
Hoops and sheets	29,304	28,735	24,679
Bar, angle, bolt, and rod	9,454	16,143	7,80

American Pig.—So far as the volume of business is concerned, it has been slightly better this week than last, but the tone of the market can not be said to have improved in any manner. Consumers do not complain of prices, but their requirements are limited, and such is their apathy that a further decline appears inevitable unless the restriction of the output begins to tell at an early date. We quote $20.50@$21.50 for No. 1, and $19@$20 for No. 2, with mill irons, which are more active, at $17.50@$18.50, all at tide-water. Bessemer pig is dull, with a weakening tendency, due to lower advices from abroad. We quote nominally $20.50. Spiegeleisen is quiet, being offered at $30.25.

At the Exchange, the following sales were recorded:

Wednesday, 100 tons No. 1, at $19¾.

Scotch Pig.—The demand here is light, and the advices from the other side rather discouraging. On the other hand, arrivals are light and are generally disposed of before they reach this port. Importers claim that they can not shade current prices without loss.

We quote ex ship and to arrive: Coltness, $23@$23.25; Langloan, $23@$23.25; Summerlee, $22.50@$23; Eglinton, $20.50@$21; Glengarnock, $22; Dalmellington, $21.

At the Exchange, the following lower cable quotations were received to-day: Coltness, 55s. 6d.; Langloan, 56s.; Summerlee, 54s. 6d.; Gartsherrie, 53s. 9d.; Glengarnock, at Ardrossan, 53s.; and Eglinton, at Ardrossan, 46s. 9d. Warrants at the Exchange to-day were 45s. 1d.

Rails.—Sales are reported of 8000 tons of rails; one lot of 3000 tons, at Pittsburg, at $37, which also is given out as the figure for the other lot. The market has a weakening tendency, as the mills are approaching the time when their orders are exhausted, and it is feared that then, in their eagerness to secure business, they will be ready to accept lower figures, which, indeed, rumor has repeatedly announced, and which we have reason to believe is not far from wrong. The mills will probably be loath to shut down, and therefore lower figures are looked forward to. We quote nominally $36.50@$37.

Old Rails.—Business light, with quotations at $22.50@$23 at tide-water for Ts.

Scrap.—We quote $23 ex ship.

Philadelphia. October 26.

Several holders of inferior pig-iron are endeavoring to crowd stocks on the market at concessions from the rates prevailing heretofore, which are $21@$22 for No. 1 Foundry and $19.50@$20 for No. 2; $18@$18.50 for Forge. Schuylkill irons have been sold at $17, shaded at furnace. A few small lots have sold at this price and with options for larger lots, which will probably be placed during the coming week. The market is very weak and dull, and three or four companies announce it to be their intention to blow out more furnaces. The movement in Foundry is still in small lots, at $21@$19.50, although there are sales at $20.50@$19.

Foreign irons are very weak. No sales of Bessemer have been reported, and the offers made a week or two ago have been withdrawn. Handlers of Scotch iron are selling a little more freely, but at concessions of 25 cents.

Merchant bar iron is still weak and dull, and a further restriction in output has taken place during the week. Mills in the interior are taking fewer orders, although they are offering to take business at concessions even from the low rates current. There is no difficulty in getting iron at 2c. Store demand is falling off, and the orders at mills are for small lots. Some offers have been made for large lots, but the terms are not acceptable. Western iron has been heard of once more in this market, and has been delivered under 2c. A few sales of skelp are probable this week. Sales of common iron have been made at 1·75c.

Plate and tank iron are moving steadily, and mills are well supplied with orders. Prices are 2·30@2·40c. for Plate; Shell, 3c.; and Flange, 4c.

There is a fair movement in structural iron, and heavy deliveries on summer contracts are going on. Two or three specifications have arrived this week, and business will probably be closed next week for winter delivery. Beams and Channels are 3·40c., and some sales have been made at a little less. Tees, 2·75c.; Angles, 2·40c.

There is a disposition to take a little less for steel rails for winter delivery, and it is probable that business will be done next week at $37, shaded; $36.50 is likely to be taken for large lots. Buyers appear determined to pay no more.

Sales of old rails have been made at $23.25, to arrive. Average quotations, $23.50. Double Heads have been offered at $25.50, and offers have come in at $25. Crop-Ends are nominal at $23.25, with offers at 50c. less.

Pittsburg. October 24.

There are indications of more labor troubles in iron-making and in mining. The Edgar Thomson management has discharged 100 men, and it is said that wages will be reduced at the opening of the year. Workmen have been discharged from quite a number of mills, and there are rumors of a probable restriction of output, unless demand should improve during the next thirty days. Sales of pig-iron have been made at $17.50 as an average for Gray Forge and White and Mottled, $20@$21 for Foundry, $21 for Bessemer, and $29 for C. B. charcoal. But little anthracite and charcoal is selling, the preference being for lake ore iron, smelted with coal and coke. City furnaces are asking $17.50@$18, and have refused lower offers. The outlook for forge is better, but foundry continues weak and dull. Muck Bars have declined to $33. Manufactured iron is in better demand; assorted bars, 1·80@1·90c. Nails, $2.70. Buyers are covering only current requirements. There are offers for large lots at $2.60. Several good sales of wrought pipe have been made. Old rails are quoted at $24.50. Steel rails, $37.50. Merchant steel is weak and dull. Railroad track supplies are active at $2.60 for spikes and $1.90 for splice bars. The glass trade is unchanged. The coke trade is improving, and prices at ovens are $1.10. There are now 1094 ovens idle and 8102 at work.

COAL TRADE REVIEW.

NEW YORK, Friday, Oct. 26.

Anthracite.

With the exception of steam coal, for which there is some demand on the basis of about $4.25, there is very little that is new in the trade. It continues dull and lifeless, with some pressure to sell and very little disposition to buy. About the beginning of December, the trade usually falls off considerably, and prices weaken. The indications now are, that the heavy output of the current year will bring the opening of this season fully a month earlier, and well informed observers of the trade look for a further easing up in the first week of November. It remains to be seen whether the pressure will become so great as to necessitate a restriction of the output. Buyers apparently cling to the conviction that they will have an opportunity to purchase to better advantage then, and are persistently keeping out of the market, with the exception of those who must stock up before navigation closes.

Bituminous.

Except occasional rumors of low prices, there is nothing to disturb the apathy of the bituminous coal trade. To all but a few, the season has been very disappointing.

Cleveland.

There is a great commotion in the Massillon District just now, over the discovery of coal at 400 feet below No. 1, or the lower coal measure, as given by the geological reports. Having noticed reports asserting that a six-foot vein had been discovered, I took the trouble to go to Canal Fulton, and learn all about the "great find." I learned that two men, John McFadden and John Campbell, both miners and living at Fulton, having heard that a man who sunk a hole in that vicinity some sixty years ago, in prospecting for salt, had gone through several feet of coal, had secured leases on about 1000 acres lying along the Tuscarawas River to the north and west of Canal Fulton. They selected a spot about one and a half miles up the river and on the west side, in a run bottom, and began drilling in an abandoned hole then about 200 feet deep. After working "on and off" all summer, they finally struck what they thought to be coal, and after some preliminary arrangements and agreements with lessors had been effected, took a number of reputable citizens with them to witness the work of drilling through the coal. I talked with Mr. Campbell and two or three of the men who witnessed the work, which was done on Monday, the 15th inst. All report six feet of coal, and samples of the drillings which I saw indicate a good bituminous coal, resembling in general appearance the Massillon or No. 1. Mr. Campbell says that they found nothing resembling or answering to the Waverley stone; but I found that, on account of the rude character of the drilling apparatus and want of technical knowledge of the workmen, no definite idea of the formation could be obtained. Two or three prospecting companies have been formed, and the lands "all round about" have been leased, and no doubt some more systematic prospect-work will be done. It is to be hoped that a diamond bit drill will be used next time, and the cores preserved. Some of the old heads think it a freak of nature, and that further investigation will prove the area very limited; but no one who knows the parties or witnesses doubts that a bed of coal was struck as reported. It would seem to be a very capricious freak of nature to deposit from five to six feet of coal at that depth in a small pocket; but time and thorough investigation will bring out the facts.

Pittsburg.

Coke is steady and unchanged at former prices, $1.05@$1.15, free on board. There have been no more "gobbles" by Frick & Co. since my last, and the next freight pool is as far from settled as ever. The illness of President Roberts, of the Pennsylvania Railroad, has interfered with the meetings of the pool lines. Meanwhile, the Vanderbilt end of the Pittsburg & Lake Erie Railroad, the Pittsburg, McKeesport & Youghiogheny Railroad, began, on Friday last, the running of regular coke trains over its substantial and costly line. The rates were not different from those previously in force, the new road operating as an extension of a pool road, the Pittsburg & Lake Erie. Those in the best position to know state that a new freight pool can be ultimately arranged between the lines without danger of a rupture, but that there are so many matters to consider and so many complications arising that a number of meetings must be held and an unusual amount of time consumed. The demand for coke is good, and cars are reported very scarce for West-bound coke.

Horsford's Acid Phosphate.

Unanimous Approval of Medical Staff.

DR. T. G. COMSTOCK, Physician at Good Samaritan Hospital, St Louis, Mo., says: "For years we have used it in this hospital, in dyspepsia and nervous diseases, and as a drink during the decline and in the convalescence of lingering fevers. It has the unanimous approval of our medical staff."

ROTHWELL'S

Great Map of the Wyoming Valley.

This, the most elaborate and accurate topographical map ever made in this country, outside of the Coast Survey, covers an area of TWO HUNDRED SQUARE MILES, and the work upon it cost over $12,000. It represents a coal-field which produced in 1882 over 13,000,000 tons of Anthracite. The Map was constructed altogether from original surveys. Every Road, Colliery, Building, or land or property line existing at the time is accurately located. The surface configuration is shown by CONTOUR LINES TEN FEET APART, VERTICALLY; and the elevation of every point above sea-level is given

But a small edition of this Map was printed, and the plates were then destroyed.

A few copies are for sale

Price: On thick heavy paper $25

On bond paper, for mounting 25

The six sheets can be mounted separately, or in a single roll 15 feet long by 42 inches wide.

LAST week, we printed in a letter from a correspondent a report of the alleged discovery of coal near Clinton, Summit County, O., which was causing considerable excitement throughout that State. The opinion was advanced by Professor ORTON that possibly it might be albertite, while others held that it might be the lower coal of the slate series. Mr. ANDREW ROY, the State Mine Inspector, however, believes that the hole was salted, and some of the points he brings forward certainly make it look as though such an operation had been attempted in a very crude way. They pump a material conta ning 80 per cent of carbon out of the hole in pieces as large as the thumb, a size which no true borings could furnish.

AN anonymous correspondent has requested us to insert a price-current of "the numerous minor metals, which, though not largely dealt in, are generally matters of considerable interest to those having to do with ores and metallurgy." We are fully aware of the interest attaching to this subject, and to show how such figures may occasionally become important, we may state that only recently a gold company has entered the market with arsenic products, which it now offers for sale. We shall be pleased to make an effort to collect the data which our correspondent desires to obtain, if he will give us a list. It must be stated, however, that the minor metals are generally controlled by a few parties, who allow very little correct and complete information to reach any but a limited public.

THE reports of the discovery of tin ore in different parts of the country are multiplying. The Alabama mines, now we believe temporarily idle for want of additional working capital to carry out some improvements, have been followed by the Black Hills tin deposits, so elaborately described by Professor BLAKE in these columns. Some time since, there floated to us rumors of discoveries of the same metal in Virginia. They are now authoritatively confirmed by Prof. HARRY D. CAMPBELL, of the Washington and Lee University, Lexington, Va., who has reported on the subject in a letter to *The Virginias*, an advance-proof of which has been kindly sent to us by Major JED HOTCHKISS, the editor. The ore, which was seen in place by Professor CAMPBELL, is found on Painter Mountain branch of Irish Creek, Rockbridge County, Va., about one and a quarter miles from the Nelson County line. It is cassiterite in a vein running east and west, several inches thick. The country-rock consists principally of large crystals of quartz and feldspar, smaller crystals of mica, and some mica.

FROM California come again strong complaints concerning the present status of the quicksilver industry, which is languishing under low prices, apparently brought about principally by the extensive importations in anticipation of the duty of 3·6 cents per pound under the new tariff. During the first six months of 1882, the imports were 4781 flasks ; for the entire year, the heavy importations of the second half carried them up to 13,116 flasks ; and in the first six months of 1883, they ran up to 12,982 flasks. It might be argued that the depression due to this heavy stock would be likely to be only temporary. But the course of prices abroad discourages any such hopes. In September of last year, the price in London was £6, but it has since declined to £5 5s., while here it has dropped to 34·5 cents per pound. Nor does there appear to be any prospect of an early recovery, because there are fully 100,000 flasks of quicksilver in stock in England. Under such pressure, the mines in this country are steadily losing ground. The production, according to the leading authority on the subject, Mr. J. B. RANDOL, of San Francisco, has been as follows since 1873 :

PRODUCTION OF QUICKSILVER IN CALIFORNIA.

	Flasks.		Flasks.
1873	27,642	1878	63,880
1874	27,956	1879	73,684
1875	50,250	1880	59,926
1876	75,074	1881	60,851
1877	79,396	1882	52,732

For the first nine months of the year 1883, the production of the different mines was as follows :

	Flasks.		Flasks.
New Almaden	21,819	Great Eastern	1,377
Napa Consolidated	4,482	New Idria	1,132
Great Western	3,104	Various mines	1,67
Sulphur Bank	2,182		
Redington	1,573	Total	35,836

At this rate, the total production of the year will probably not be higher than 48,000 flasks, and this is only reached because the largest miners are straining their capacity to make up in their returns by a heavy output for the falling off in price. The result may be readily foretold. Nearly all the mines will stop dead-work, exhaust their resources, and close down, or will continue to make as heavy drains on the purses of their shareholders as the latter will submit to. The producers see only one way out of the dilemma to save the heavy amount invested in mines and plant and now threatened with ruin. They will probably ask, and it is hoped will obtain, an increase in the duty to 10 cents per pound.

THE meeting of the American Society of Mechanical Engineers, held in this city this week, was fairly successful. The number and standard of the papers was not so high as those interested in the welfare of the society might wish ; but this, we happen to know, is due principally to the fact that a number of very interesting papers were withdrawn a short time before the meeting, because the authors could not complete them.

There is one matter which occupies entirely too much of the attention of the meetings not to affect the interest and therefore the future of the society unfavorably. There are eternal bickerings as to its by-laws. There is altogether too general a disposition among the members to take a share in tinkering with the constitution, insisting on its being carried out to the letter, however unimportant the points raised may be. The Society of Mechanical Engineers should follow the example of the Mining Engineers—elect a good council, have faith in its wisdom and zeal, and leave the management of the affairs of the society to it. As it is now, hardly a session is passed without some unprofitable discussion, which at best discourages those intrusted with executive functions, because they are subject to a constant and often captious criticism. While we have no doubt that the motives of all are the very best, and while it is true that generally young societies struggle to some extent with questions of organization, it looks to the unbiased spectators as though the greatest danger to

Digitized by Google

the future of the society comes from those who are so anxious to make its organization their ideal of perfection. The Council of the Society of Mechanical Engineers is composed of gentlemen many of whom have had a wide experience in the affairs of kindred associations. Throw upon them the responsibility of executive details, and devote the time of the sessions to the business that members have come long distances for. Engineers do not travel hundreds of miles to listen to a debate on some amendment to the by-laws. They want to learn what the best of their fellow-engineers have accomplished; in what direction they are working; how they are going at it; what obstacles they have met, and how they propose to overcome them.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

Water-Jackets versus Brick Furnaces in Copper Smelting.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: In Mr. Douglas's interesting paper on the metallurgy of copper, printed in *Mineral Resources of the United States*, Washington, 1883, he says: "The data are not yet available for determining the consumption of fuel in water-jackets and brick furnaces, respectively." When we were considering that question, Mr. Douglas gave it as his opinion that water-jackets were at least as economical as brick furnaces. We have come to believe they are more so, and offer these results from one we have in operation here. Jacket, 44 inches diameter at bottom, by 48 inches at top; hight, 84 inches. Six tuyeres of 2¼-inch opening. Blast, 7 ounces per square inch. Smelting roasted sulphurets. Charge, 700 pounds ore and 80 pounds Connellsville coke; both weighed for each separate charge. With this burden, the furnace melts about 80,000 pounds of ore daily. During the week just past, we used a mixture of equal parts of Boston gas-coke and Connellsville coke. Including loss in wagon transport and otherwise, the week's account showed this furnace had melted 7·85 pounds of ore with one pound of mixed coke. And besides, it melted about 18 tons of slag from matte smelting, for which no fuel was allowed in the charge.

We should like to see some results from brick furnaces on similar ore.

WILLIAM GLENN, Agent
SOUTH STRAFFORD, VT., Oct. 31. Elizabeth Mining Company.

Desilverization o Refined Lead.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: At the works of a certain smelting and refining company, where the Parkes process is used, when the silver in lead goes down to less than 0·2 ounce per ton, the operation is considered finished, as it would not pay to attempt any further desilverization with zinc. The assayer then usually sends a written order to the kettle-men to "steam 15 or 30 or 45 minutes and tap," the time for steaming depending on the amount of silver left in the charge.

The other day, the foreman of the refining department, who had had much practical experience in silver smelting and refining, first conceived an idea that when a charge of base bullion, after repeated zinckings, had come down to 0·4 or 0·5 ounce of silver per ton, he might dispense with the usual zinc at this point and substitute the use of steam, in hopes that he could save the zinc as well as four or five hours' time. I then had daily charge of the chemical analyses and "kettle assays" which control all the operations in the refining department; and that day I gave an order for the usual quantity of zinc for say 0·3 or 0·4 ounce of silver per ton, which I had just found by assay. But the foreman reversed my order, and directed the kettle-men to steam 45 minutes instead. At the end of that time, samples were sent right off to me to assay, to see if the amount of silver left had been successfully reduced to below the specified minimum of 0·2 ounce per ton. In nine out of ten cases, such samples assayed much too high, very often as high as 2 or 4 ounces, and sometimes even higher. That the lead could become richer after steaming, should be considered ridiculous and absurd, even though experiments on other charges, under some conditions and circumstances, gave similar results; and I was at a loss how to account for such high assays, especially as I was told that they had taken off the skimmings before sending their samples to the assay-office.

I have been thinking carefully over the matter ever since, and am now strongly of the belief that those samples I assayed had been taken out too early, and out of a kettle while yet too hot. In the melted lead, when heated by steam, quite or nearly all of its silver contents will go upward and be more concentrated in the upper part of the lead; and as samples are necessarily taken out from the top, they will assay too high, and therefore can not represent the average value of the soft metal in silver. If they wanted to procure fair samples, they must have waited until the kettle became sufficiently cool, when the silver would have been uniformly distributed throughout the lead again.

Exceedingly hot and moderately hot lead will assay differently, as any one can find by careful experiments; the former invariably giving higher results than the latter. But the latter is correct and truthful as to the average richness of the metal.

It has recently occurred to my mind that, if silver is really concentrated in the upper part of the lead when steamed, this fact might be utilized with financial profit. When the kettle becomes exceedingly hot by means of steam, you may ladle the uppermost portion (say one half, or rather, one quarter) of the charge out of that kettle into a fresh kettle; when the latter becomes full from subsequent operations on other charges, you will have the lead rich enough to allow the use of zinc for the extraction of an additional quantity of the precious metal. In the former kettle, you may tap the remainder of the lead at once, and send it to the market as "extra refined lead."

GEORGE T. DOUGHERTY.
2623 TEXAS AVENUE, ST. LOUIS, MO., Oct. 20.

The Electrolytic Process, as Described by C. O. Mailloux.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: The volume just published by the United States Department of the Interior, *Mineral Resources of the United States*, contains so many excellent monographs that Mr. A. Williams, Jr., Chief of Division of Mining Statistics and Technology, deserves much praise for his good judgment in the selection of the men who have assisted him in his difficult task. There is one article, however, which I shall take the liberty of criticising, namely, "Electrolysis in the Metallurgy of Copper, Lead, Zinc, and other Metals," by C. O. Mailloux.

The literature on this subject is exceedingly poor, and entirely worthless, as far as practical application of this process is concerned. Those who know something about it keep their experience a secret, and those who know nothing about it are the most eager to rush into print. Mr. Mailloux belongs to the latter class, and I propose to discuss the most glaring misstatements of his paper.

Page 639: "*Copper by Electricity at the Oker Mine.*—In Germany, at the royal mines of Oker, the extraction of copper out of the solutions resulting from the working of copper mattes is done at present by the agency of electricity. . . . Three Siemens machines are run day and night, the current being passed through ten or twelve precipitating-vats containing the solution. The anodes and cathodes used are of lead or other metal not soluble in the solution. The average product is 25 kilograms of metallic copper per vat per twenty-four hours, or between 250 and 300 kilograms for each machine, with an expenditure of from 8 to 10 horse-power per machine."

In the first place, there are no "royal mines of Oker." The metallurgical works at Oker are the principal ones which reduce the ores from the Rammelsberg mine, near Goslar. The process, as described, only exists in the imagination of the writer. He is fully justified in asking: "Why use the current from an external source at all? etc. . . . . It would be better to use more vats, and larger ones, and substitute the process of MM. Dechaud and Gaultier." But I ask myself: Why use the process of MM. Dechaud and Gaultier, when the copper can be precipitated by simply bringing the solution into contact with scrap-iron? The electrolytic works at Oker part copper, containing silver and gold, which were formerly (and are, in part, now) granulated and dissolved in dilute sulphuric acid for the manufacture of copper vitriol. There are five Siemens machines, each requiring eight horse-power, and capable of precipitating each 300 kilograms of copper in twenty-four hours.

Page 641: "*The Elkington Process.*—The current causes the copper to be dissolved out of the matte plates; and, at the same time, it is deposited at the cathodes in equal amount. Almost all the impurities ordinarily present in the anode are insoluble in the solution, except iron." . . .

Here the idea is conveyed that at Elkington's works anodes of copper matte are treated. This is not correct. The only material which can be, and is, treated by the electrolytic process with economy is metallic copper. It is even unprofitable to subject black copper to the process. The copper, before being cast into anodes, should be, and is, first refined, and made as pure as possible for various reasons, namely: 1st. To get smooth anodes. 2d. Because pure copper is a better conductor, and polarization is reduced to a minimum. 3d. On account of conserving the solutions as long as possible. Mr. Mailloux does not seem to be aware of the fact that arsenic goes into solution, and is, indeed, the greatest enemy of the process. Arsenic is precipitated on the cathode when it obtains even a moderate concentration in the solution. It has been found that, with very low volts of the current, arsenic commences to precipitate sooner than if a current of higher volts is used. Bismuth will also go into solution, and precipitate on the cathode, if the copper, in refining, has been "over-poled." If the copper contains antimony and oxygen, the bismuth will be found as a precipitate of antimonate of bismuth.

Page 644: "Thousands of tons of Chilian copper mattes, containing traces of gold and silver, find their way to Swansea, and the greatest portion of them is refined by electrolysis. The production amounts to several tons of pure copper a day in each place."

Will Mr. Mailloux oblige the readers of the JOURNAL by giving the names of the works at Swansea in which such large quantities of copper "with traces of gold and silver only" are refined by electrolysis?

Page 644: "Only a little labor is required for attention in such accessory operations as casting the plates, emptying and filling vats, etc. The power required need not be very great. An expenditure of 20 horse-power would, no doubt, suffice to produce enough current by means of dynamo-electric machines to refine as many tons of copper a day, without necessitating a plant of undue or undesirable size. The solution, it is seen, is not costly; moreover, it is durable. It undergoes no changes by use, except that it becomes charged with iron and other impurities derived from the crude copper."

This statement is astonishing on account of its absurdity. It is surprising that Mr. Mailloux could make it after giving, in previous pages, a correct *exposé* of the effect produced by connecting the electric cells "parallel" or "in series," and after stating the injurious effect of polarization. It is to be presumed that at Oker, where a few tons more of copper in rotation would be no object, they have reached a practical limit of arranging the plant "in series." Hence, we may assume that it is not practicable to precipitate with an expenditure of 20 horse-power much more than 750 kilos of copper in twenty-four hours. Mr. Mailloux, however, has no doubt that he can precipitate with 20 horse-power 20 tons of copper per day, and that without necessitating a plant of undue or undesirable size. Taking the experience at Oker as a basis for calculation, works of 20 metric tons daily capacity would require 67 *Siemens machines*, 536 *horse-power*, and an *area* of about 20,000 *square meters* to set up the plant. Concerning the durability of the solution, I have already stated that it depends principally on the absence or presence of arsenic. That the labor of attending to such an extensive plant forms also a considerable item of cost, requires no further demonstration.

On page 646, we find a rather long and superfluous discussion of Cassel's process. Any person familiar with the subject who reads Cassel's patent specification will see at once that there is nothing in it, and that it is not worth three pages of criticism. But here again the facts are not correctly stated in some respects. The electrolytic plant put up in 1882 at Mathey & Riotte's metallurgical works for the purpose of refining silver and gold bullion was constructed by P. Holder, a Mr. Hamilton furnishing the capital for the enterprise. Mr. Holder, as agent for André, had

Digitized by Google

previously carried out a series of experiments in the electrolytic refining of copper at the works of Pope, Cole & Co., Baltimore. The Siemens machine, imported at the time by Pope, Cole & Co., was the one set up at Mathey & Riotte's. Mr. Holder had adopted a modification of André's plant. On account of financial difficulties, this plant was never completed or operated by Holder. How much Messrs. Mathey & Riotte experimented with it I do not know. One fact only is certain, that they never obtained a sufficient quantity of bullion to experiment on a large scale. The same plant was subsequently bought by the United States Bullion Refining Company, and set up in Cortlandt street by Cassel, with the addition of his supposed improvements. It proved to be a total failure, as stated by Mr. Mailloux.

The account of Keith's process for desilverizing lead bullion is the most interesting and best chapter of the paper. It is to be hoped that when the new works at Rome are in operation, Mr. Keith will be able to demonstrate to lead refiners the economy of his ingenious process, which, so far, he has not done.

In concluding his paper, Mr. Mailloux refers to electrolytic assaying. He says: "A French chemist, M. Alfred Riche, has applied the idea successfully to the assay of copper, lead, zinc, manganese," etc. It would have been more appropriate to state that the electrolytic method of assaying, so far as copper is concerned, is now generally introduced everywhere. That M. Riche is not the originator of this method, but only one of the many co-workers in its perfection, is well known to all who are familiar with the literature of this subject.

Finally, I wish to state that an electrolytic plant of 800 pounds daily capacity is in successful operation at Balbach's works, Newark, N. J., where copper rich in silver and gold is parted. Mr. Balbach uses the pure electrolytic copper for precipitating cement silver in refining silver-gold bullion by the sulphuric acid process. C. A. STETEFELDT.

THE NEW YORK MEETING OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

The widespread interest shown in the work of this young society is evidenced by the comparatively high percentage of its members attending the meetings, fully one third taking part in them. At the opening session, fully one hundred gentlemen gathered in the rooms of the American Society of Civil Engineers, hospitably tendered for the purpose. After a few words of welcome from the President, Dr. E. D. Leavitt, Jr., of Cambridgeport, Mass., Mr. Thomas R. Pickering, of Portland, Conn., read a paper on

AMERICAN MACHINERY AT FOREIGN EXHIBITIONS,

in which Mr. Pickering, who has been a commissioner at almost every leading international exhibition for the last quarter of a century, gave a series of reminiscences. He dwelt upon the advantages which have accrued to manufacturers of machinery and the country at large. He gave some striking instances of the lack of faith of official representatives of the United States in the work of their own country. Thus, at the Paris Exhibition, its representative asked that power be furnished by a French engine firm, as he evidently believed that American engines could not be depended upon to furnish power with regularity. A French engine did actually drive the machinery of the American exhibit, yet a Corliss engine, although hidden by it, attracted more attention and obtained a gold medal, and its French rival was awarded only a silver medal. He dwelt on some striking cases of piracy, which a number of the gentlemen present referred to in the discussion following.

Mr. A. C. Hobbs, of Bridgeport, Conn., told a number of amusing stories concerning his experience in showing European lock-makers how difficult it was to baffle the ingenuity of an American mechanic.

At the invitation of the local members, the society partook of a supper served in the rooms of the Society of Civil Engineers.

Among those present at the meeting we noticed the following: George J. Alden, Worcester, Mass.; T. R. Almond, Brooklyn, N. Y.; W. S. G. Baker, Baltimore, Md.; W. J. Baldwin, New York City; S. W. Baldwin, New York City; W. M. Barr, Cleveland, O.; P. Barnes, Springfield, Ill.; J. C. Bayles, New York City; T. Bergner, Philadelphia; A. Betts, Wilmington, Del.; Charles E. Billings, Hartford, Conn.; G. M. Bond, Hartford, Conn.; W. G. Cartwright, Hoboken, N. J.; Z. B. Coes, Altoona, Pa.; A. W. Colwell, New York City; A. B. Couch, Philadelphia; D. P. Davis, New York City; C. P. Deane, Holyoke, Mass.; J. E. Denton, Hoboken, N. J.; W. W. Drummond, Louisville, Ky.; W. F. Durfee, Bridgeport, Conn.; T. Egleston, New York City; C. E. Emery, New York City; Faber du Faur, New York City; John Fritz, Bethlehem, Pa.; Francis E. Galloupe, Boston, Mass.; Edmund le B. Gardner, Passaic, N. J.; A. A. Goubert, Jersey City; John J. Grant, Flushing, N. Y.; Howell Green, Jeanesville, Pa.; Robert Grimshaw, Philadelphia; A. F. Hall, Boston; F. A. Halsey, New York City; S. A. Hand, Tough Kenamon, Pa.; F. F. Hemenway, New York City; M. P. Higgins, Worcester, Mass.; H. A. Hill, Boston, Mass.; J. C. Hoadley, Boston, Mass.; J. L. Hornig, Jersey City; R. W. Hunt, Troy, N. Y.; F. R. Hutton, Secretary, New York City; W. Johnson, Lambertville, N. J.; H. C. Jones, Wilmington, Del.; C. Kirchhoff, Jr., New York City; L. G. Laureau, New York City; E. D. Leavitt, Jr., President, Cambridgeport, Mass.; W. Barnet le Van, Philadelphia; L. F. Lyne, New York; De Courcy May, Cambridge, Mass.; George W. Maynard, New York City; Alexander Miller, New York City; Thomas R. Morgan, Sen., Alliance, O.; William H. Odell, New York City; E. H. Parks, Providence, R. I.; W. E. Partridge, New York City; T. R. Pickering, Portland, Conn.; C. T. Porter, New York City; T. W. Rae, New York City; W. J. Root, Brooklyn, N. Y.; Joshua Rose, New York City; P. B. de Schweinitz, South Pueblo, Colo.; W. N. Shock, Washington, D. C.; G. H. Smith, Providence, R. I.; Oberlin Smith, Bridgeton, N. J.; G. S. Strong, Philadelphia, Pa.; J. E. Sweet, Syracuse, N. Y.; H. R. Towne, Stamford, Conn.; R. H. Thurston, Hoboken, N. J.; J. B. Webb, Ithaca, N. Y.; S. Webber, Manchester, N. H.; S. S. Webber, Lawrence, Mass.; A. Webster, Waltham, Mass.; G. W. Weeks, Clinton, Mass.; W. H. Weightman, New York City; S. T. Wellman, Cleveland, O.; F. M. Wheeler, New York City; W. H. Wiley, New York City; Alfred R. Wolff, New York City; Horace B. Miller, New York City; Carl Angstrom, Worcester, Mass.; William Betts, Wilmington, Del.; W. T. Capen, Stamford, Conn.; A. Sinclair, New York City; and J. F. Holloway, Cleveland, O.

It will be noted that this list contains a large number of representative men.

THE SECOND SESSION

was held on Thursday morning, the first hour being occupied by routine business, a brief report by the council, a more lengthy document from the treasurer, and a report by the Committee of Tests, presented by Professor Egleston, who urged the appropriation of $200 for the republishing for distribution of the report at the Philadelphia meeting of the society. The low condition of the treasury of the society gave rise to some doubts as to the advisability of incurring this additional expense, and led to a somewhat rambling debate in which, incidentally, the question was raised by Mr. Towne, whether it would not be best to increase the fees to $12 per annum, to provide for current expenses. Mr. J. Bogart, Secretary of the American Society of Civil Engineers, gave a statement of the action of his society in the matter. He gave some account of the conferences held with General Benét, Chief of the Ordnance Department, whose co-operation was secured. The society now takes the position that it will do all it can to aid the Chief of Ordnance in his work of testing, until a bill can be passed for the appointment of a Tests Commission. Finally, after some talk, the grant of $200 asked by the Test Committee was voted.

After a report by the Publication Committee and the Committee of Gauges and Standards, Mr. James C. Bayles addressed the meeting in behalf of the Holley Memorial Committee. He stated that the treasurer had collected the amount necessary to build the monument, the subscription having reached the required sum, so that the execution is now assured. Mr. Laureau, of New York City, formerly associated with Mr. Holley, is now working on designs for the base. Mr. Bayles submitted a letter received from Dr. Raymond, which the committee did not feel authorized to reply to. Upon motion, the council was given authority to instruct the committee to co-operate with the American Institute of Mining Engineers and possibly the Society of Civil Engineers, in reference to the publication of the Holley Memorial Volume.

Mr. Bayles also spoke of the possibility of a visit of the British Iron and Steel Institute to this country in 1884, the members coming to this country after attending the meeting of the British Association in Canada, and a resolution to issue an invitation to them was passed.

THE AFTERNOON SESSION

was opened by a paper by Mr. W. F. Durfee, of Bridgeport, Conn., on

A POWER CRANE

of six-ton capacity, designed by him in 1867 for the machine-shop of the Milwaukee Iron Company, which was probably the first crane of that capacity built in this country.

The paper was highly commended by Mr. Towne, of Stamford, Conn., who, in the light of the present state of the art, had only a criticism to offer on two points of minor importance.

Mr. Carl Angstrom, of Worcester, Mass., explained the construction of

A NEW VALVE MOTION,

belonging to the class, like those of Joy, Brown, and Marshall, known as "radial valve motions." The motion is generally accomplished by an arm, two points of which move in different curves. One point moves in a closed curve, such as a circle or an ellipse, this motion being derived from an eccentric, crank, or from the connecting-rod. The other point again moves either in an open or a closed curve, and this motion is accomplished either by levers or slides, or both combined. In the Angstrom valve motion, the difference from those previously mentioned consists chiefly in the mechanism for giving motion to the last-mentioned point of the valve actuating arm. Mr. Angstrom believes that this motion can be used with advantage on engines running chiefly in one direction. The pendulum links and connections could then be proportioned so as to give a good steam distribution and equal cut-off at each end of the stroke.

Prof. R. H. Thurston, of the Stevens Institute of Technology, and others, asked Mr. Angstrom a series of questions, and dwelt upon special features of the design.

Prof. Robert H. Thurston, of the Stevens Institute of Technology, Hoboken, N. J., presented a paper on

THE PRESSURE ATTAINABLE BY THE USE OF THE DROP-PRESS,

now so extensively employed in the process of "drop-forging" and in the manufacture of small parts of sewing-machines, fire-arms, and light machinery.

In the course of an investigation of the efficiency of drop-presses lately made by the Mechanical Laboratory of the Stevens Institute of Technology, it was found that the most efficient presses experimented with had an "efficiency," as the term is technically used, of 90 per cent. A few figures from a table given were computed upon the assumption that this efficiency can be reached, and exhibits the mean pressure attained when the piece attacked is crushed to the amount of $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$ inch respectively. These figures are seen to be simply enormous, and the power of this form of press is evidently limited only by the rigidity of its parts and their strength.

The figures given for the pressures reached when the compression is one sixteenth of an inch can only be obtained when the anvil is so set and of such material that the yielding there occurring can not absorb more than the allowed 10 per cent of the total work of the falling mass. The same remark applies to the table generally; but the loss may always be expected to fall within the assumed figure for the smaller weights and lesser hights fallen through; if the machine is well built and the anvil and foundation are of ample size and rigidity for good work, it is improbable that the higher figures can be readily obtained; also, if proper precautions are taken in the setting of the press.

The intensity of pressure attainable is evidently determined by the area of the surface exposed to the action of the drop, and this in turn determines the distance through which crushing may occur. The figures given in the table are total pressures, and the mean intensity of pressure corresponding to these amounts is to be obtained by dividing the total pressure as shown in the table by the area of section of the crushed piece, or by the mean area opposed to the crushing action during the operation. The proper comparison is that of the energy of the falling weight with

Digitized by Google

the "resilience," elastic or total, or both, of the mass on the anvil or in the dies.

PRESSURES OF THE DROP-PRESS.—(EFFICIENCY 90 PER CENT.)

The limit to the resistance of any mass on the anvil is found at the pressure at which the metal will "flow" continuously. This pressure varies with not only the kind of metal, but with every variation in the chemical composition, the physical structure, or the form and method of support of the piece. For general use, the value of this "modulus" may be taken at about the value of the shearing resistance of the material. For soft wrought-iron, for example, it may be taken at about 50,000 pounds per square inch (3515 kg. per sq. cm.), for moderately hard iron at a figure 20 per cent higher, and for pure copper at about one half the latter figure. There is, however, a great difference in the behavior of the two metals under pressure. The former has a distinct elastic limit in its original state which becomes "exalted," as was shown by Professor Thurston some ten years ago, when the piece is distorted, and becomes approximately equal to the maximum force, producing change of form, remaining permanently altered. The metal thus transformed does not yield subsequently to any less pressure. It will not flow under any pressure less than that which is required to produce distortion immediately upon its application. Copper, however, has no true and measurable elastic limit in its original condition as found in the market, and it does not flow under the continued action of forces far less than those required to produce rapid and continuous distortion by steady pressure. A load which produces no visible effect when first applied will after a time be found to have caused a very decided and often a very extensive alteration of the form of the mass. This is also a now well-known property of some kinds of brass and of many other metals belonging to what Professor Thurston has called the tin class, to distinguish them from the metals of the iron and steel class, which do not exhibit this treacherous behavior. This difference is of some importance, not only as indicating the best method of working them, but also as showing that the first of these two classes is a safer class to deal with where the metal is to be used in the carrying of heavy and unintermitted stress than is the second class.

Another important distinction between these two classes is, as indicated by the results of investigations made by Professor Thurston, that the "iron class," which includes all the irons and all of the steels, offers more resistance as the rupturing action is slower, while the "tin class," which includes nearly all the other metals and very nearly all of the alloys that he had ever tested, yields the more readily the more slowly the distortion goes on. The second class is thus subject to that singular kind of change of form under heavy, continuous stress which is illustrated in the movement of all viscous solids—ice, for example, as seen in its flow in the glacier. This, it seems probable, may often occur under pressures far within those which are required to cause change of form in the testing-machine in the ordinary methods of test. Iron has been found by Vicat, and later by Professor Thurston, to exhibit something such a phenomenon, but only when the pressures are considerably above one half those usually found for the moduli of rupture, and this action is only seen in serious degree when the iron has been annealed and thus softened. Common merchant iron does not show any tendency to such slow and imperceptible yielding under moderate loads.

The bearing of these facts upon the value of the drop-press as a means of working iron and other metals into shape is obvious. Change of form can only begin when the elastic limit of the material is passed, and flow can only progress steadily and uninterruptedly when the pressure applied is in excess of the maximum resistance of the metal to shearing. The soft metals which belong to the "tin class" are best attacked by processes which cause a comparatively slow motion of their particles in changing form; iron and steel, on the contrary, being less resistant at high than at low velocities of flow, are best worked by methods which produce rapid distortion. Professor Kick, of Prague, has shown very plainly that this difference in the amount of work demanded by the soft metals under the two kinds of treatment may amount to a very important quantity. He finds that the distortion of bodies by the action of the hydraulic press and by the action of a hammer dealing a succession of blows to produce the same change of form consume power in the ratio, in some cases, of one to ten. It is thus evident that the hammer or the drop is to be used for those special cases in which the pressures desired can not be reached by ordinary methods, and that it is best adapted to the working of iron and steel. The hydraulic press and automatic machinery are to be preferred where they can be conveniently and cheaply used. For much of the work that is now done in our smaller kinds of manufacturing, the drop has been shown by experience to be the only machine which will give the required enormous pressures and do the work rapidly and cheaply.

The maximum area of surface exposed to pressure which will be allowable for any given amount of compression can be determined approximately by dividing the total mean pressure due to the action of the drop with the given fall, and the proposed compression by the maximum resistance of the material. The maximum area which will permit any action upon the surface is to be ascertained by dividing the same maximum pressure due the fall of the drop by the elastic limit of the metal in compression. The total work done in any permanent change of shape is proportional to the volume affected and to the maximum resistance of the material to such deformation.

What figures shall be adopted for the resistance to be calculated upon in the production of flow in metals subjected to the action of the drop-press is a question which can not be as yet answered definitely. It would seem probable that the effect of the blow may be, in the case of cold metal somewhat similar to that of cold-rolling, and this being the case, the initial resistance to flow must be taken as at least 70,000 pounds per square inch (4921 kg. per sq. cm.) and the resilience during flow at as high as 70,000 inch-pounds per cubic inch (4921 kg. m. per cubic centimeter) for good common wrought-iron. It may be safe to take the figure for hot iron, as usually worked, at less than one half this amount; for copper, in the absence of exact data, it would be well to take the work of deformation to be two thirds that of iron for pieces of small section, and expect a great increase of resistance with either metal when the surface acted upon by the drop becomes large in proportion to its thickness. Probably no very reliable figures can yet be given. Whatever the resistance may be, the drop will be very certain to overcome it, and the variation in its amount will simply determine how many blows must be struck to obtain a given amount of change of form.

Mr. Towne and Mr. Morgan, of Alliance, spoke at length on the subject of the paper, the former dwelling on the difference in different work of using a small weight and a high drop, and using a heavy weight and a low drop. The latter emphasized the same point, and called particular attention also to the necessity of guiding light hammers more carefully. Much of the loss of efficiency is chargeable to the lightness of the anvil. In this country, the general practice is not to go much beyond a ratio of one to ten of hammer to anvil weight. Krupp, in his work, increases this as high as twenty to one.

The last paper read was on

SHOP ALGEBRA,

by Oberlin Smith. It elicited no discussion.

After a number of announcements by the secretary, a debate was begun on an amendment to the rules; but in view of the late hour and the importance of the subject, it was decided to postpone the matter to the Friday night session.

The tellers then announced the following as the list of officers elected:

President.—John E. Sweet, Syracuse, N. Y.

Vice-Presidents.—A. B. Couch, Philadelphia; W. R. Eckart, San Francisco; J. V. Merrick, Philadelphia.

Managers.—W. F. Durfee, Bridgeport, Conn.; Oberlin Smith, Bridgeton, N. J.; C. C. Worthington, New York.

Treasurer.—C. W. Copeland, New York.

After the election of a number of members, Mr. J. C. Hoadley was called upon to read his paper on

A TILTING WATER-METER FOR PURPOSES OF EXPERIMENT.

Having had to make, in the course of the year, a great number of experiments in pumping water filtered through sand under various prearranged conditions, in quantities ranging from little more than one gallon in an hour to eight or ten gallons in a minute, he soon found that all commercial water-meters were wholly unsuitable for his purposes. There was required an instrument which would measure and record with all possible accuracy, and without liability to important error, the quantity of water flowing in a continuous, but pulsating and sometimes variable, stream, in accurately ascertained intervals of time. As constructed and used, the instrument is very simple and inexpensive.

Two V-shaped cups, each embracing an angle of 60 degrees, are joined together by a common side, which is, in fact, a mere partition between them, so that the two cups together embrace an angle of 120 degrees. This double cup is supported in a case upon pivots directly under the partition, turning in hollow, adjustable screws in nuts attached to the case, one on each side. When one of the outside plates of the double-V cup is in a horizontal position, supported in that position by two cork stops on which it rests, the partition between the two V-cups makes an angle of 30 degrees with the vertical, and the outside plate of the upright cup makes an angle also of 30 degrees with the vertical, but at a little greater distance horizontally from a vertical plane passing through the axis of the pivots, on account of the curve by which the outside plate is joined to the partition and to the outside plate of the prostrate cup at its lower end. But for this greater horizontal width on the outer side, there would be no tendency to tip—the upright cup would simply fill up and overflow, and there would be an end. But as the water rises in the upright cup, the prism of water outside of a plane passing through the axis of the pivots and making an angle of 30 degrees with the vertical acquires constantly increasing preponderance over the equipoise of the wedge-shaped body of water bounded by planes, each making an angle of 30 degrees with the vertical, and intersecting in the axis of the pivots. When this preponderance becomes sufficient to overcome the mechanical advantage of the prostrate cup itself over the upright cup—an advantage due to its greater leverage with equal weight—the cup will tilt, the water in the upright cup, nearly filling it, will be poured out into the case to run away through its spout, and the now empty cup, lying prone on its cork stops, will become the prostrate cup, with the greater leverage—its center of gravity being at the greater horizontal distance from the axis of the pivot. The other cup, now upright, will be filled in its turn and repeat the tilting process, and so on alternately as long as the stream flows into the cups.

The tip is very sudden, and is made with considerable force. A light spring of sheet-brass, attached to the case in the middle of its length by a piece of wood which insulates it, is connected by a binding-post with one pole of a battery, and the case itself is in like manner connected with the other pole. A bit of sheet-brass soldered to the outside of the tilting double cup, directly opposite the partition and above the case, forming a sort of cam, comes into contact with the spring in passing. This completes the circuit interrupted by the block of wood which supports the spring, and records each tip by a dot or short dash. The cam does not

Digitized by Google

come into contact with the spring until the tilting cup has acquired considerable momentum, so that the tilting is not sensibly retarded.

Mr. Hoadley had two of these meters, substantially alike, and adjusted them by flowing water through them into a tub placed on scales, counting the tips, and taking the weight and temperature of the water. He then placed one of the meters directly over the other, supported upon the tub by a suitable frame, and flowed a stream through both, the electric register recording the tips, and the scales accounting for the quantity of water. The first tip of the upper meter did not fill the lower meter to the tipping point by about one sixteenth of an inch, a little water adhering to the cup and case of the first meter; but the second tip of the first was instantly followed by the first tip of the second, and so on until the tub was filled. A repetition of this experiment gave substantially the same result—61 tips in 202¼ pounds = 3·33 pounds per tip, and at 80 degrees Fahr., 0·4 gallon per tip—231 cubic inches per gallon.

The electric register also recorded upon the same half-inch strip of paper the beats of a seconds pendulum, and, when two pumps were used, the strokes of the pumps and the tips of each meter. It was also easy to note the tips by the ear while watching the second-hand of a horse-timer, by which means the interval of time between tips could easily be observed to quarters of a second. This is not an instrument of precision. It is, perhaps, a little more accurate than a gallon measure at all practicable speeds; at slow speeds, probably decidedly more accurate, and, with proper care, no considerable error is likely to occur. When operated very rapidly, the swaying of the surface tends to accelerate or retard in a small degree the tipping of a cup nearly full, but there is no tendency to accumulation in such errors, which therefore may be presumed to balance each other, at least in some degree. The sloping covers at the ends of the case were an afterthought to prevent spattering, and were kept a sufficient distance apart to admit of taking out and replacing the tilting double cups. The curved wings under these sloping cups were a second afterthought for the same purpose, and, as it stands, the case arrests all water—there is no spattering. Of course, a suitable funnel is generally desirable to collect the water from a pump and to convey it into the cup in a stream as steady as possible, and vertically over the axis of the pivots. It is also necessary that the meter should be level, both when adjusted and when in use.

This instrument substantially weighs the water of a flowing stream, and may possibly prove useful, if strongly and delicately made, nicely adjusted, and suitably proportioned to the quantity to be recorded, for keeping the record of water used during tests of steam-engines and boilers.

The paper was discussed at some length, and in a somewhat rambling way, by Messrs. Grimshaw, Odell, E. D. Leavitt, Jr., Wolff, Emery, and others.

Prof. T. Egleston, of the School of Mines, Columbia College, New York, read a paper entitled

A MACHINE FOR OBSERVING THE PHYSICAL CHANGES OF METALS,

which was designed primarily to investigate those peculiar phases of changes in the physical properties of metals and alloys, which Professor Egleston has called the "fatigue" of metals. The machine was designed after indications of Professor Egleston, by Mr. Smith, of Messrs. Browne & Sharpe. It is like a planer, with a bed and uprights. On the bed, there is a movable carriage, which has a chuck with rotary motion, and two slide-rests to carry points. It has also a drilling-machine, to determine what Professor Langley calls the abrasive resistance, or what is too frequently called by that loose term, "hardness."

The discussion quickly drifted away from the subject of the paper, and Messrs. Hobbs, Durfee, Egleston, Leavitt, Towne, Grimshaw, and others talked about the very striking inequalities noticed in the resistance and quality of brass in a manufactured state and in the process of manufacture. The blame was partly attributed to carelessness in refining the copper, to crude methods of making the alloy, to ignorance in the design of annealing furnaces. Some very exaggerated statements, in our opinion, were made concerning differences in the quality of copper. We feel convinced that, in spite of what is said about the refining in ordinary reverberatories, and the advantage of Siemens regenerative furnaces, the raw material is not the main or even leading cause of the troubles of which brass manufacturers complain. Mr. Towne made some interesting observations as to the efforts made to secure uniformity of color of copper, zinc, and tin alloys. They picked their metal, melted the portions most closely approaching in color, went through the same operation again, and a third time, and then only they got a material fairly uniform in color.

An invitation was received from Mr. G. W. Maynard, of the Bower-Barff Process Company, to visit the Hecla Iron-Works at Brooklyn, and witness the work of coating iron with a protecting oxide.

PHOSPHORUS-MANGANESE-TIN-COPPER ALLOY.—Messrs. Cockshott & Jowett, of Thornton-road, Bradford, England, have, after a long series of experiments, succeeded in alloying manganese with phosphorus and tin and copper, producing a metal which, for tensile strength and durability, they think will be found superior to any alloy in the market. This phosphor-manganese tin may be used exactly in the same manner, and in similar proportions, as phosphor-tin—though it is better to cast at a little higher temperature—but the result will be found much superior both as regards hardness and tensile strength. Phosphor-manganese tin will be found a very convenient form in which to have the combination of manganese and phosphorus, as it will enable the brass-founder to produce the bronze of a quality exactly suitable to the purpose for which it is required by adding a greater or less proportion of copper, etc., accordingly as the bronze is required to be tougher or harder. This phosphor-manganese bronze is made in two qualities, No. 1 and No. 2, both the same price. The former is very tough and suitable for purposes where the castings are required to withstand a great strain. Mr. Kirkaldy, of London, has found this alloy to withstand the enormous strain of 34,754 pounds per square inch. The latter is for bearings and wearing parts of machinery, and is exceedingly hard, but at the same time very tough, the tensile strength being, according to Mr. Kirkaldy, 29,979 pounds per square inch.

MINING AT THE BOSTON EXHIBITION.

Special Correspondence of the Engineering and Mining Journal.

THE TENNESSEE EXHIBIT.

The extensive coal-fields of Tennessee are represented by handsome cannel coal; by some immense lumps of bituminous coal, from the Etna mines of Marion County, and the Roane Iron Company, of Rodswood, Roane County; and by some very superior coke. The coke is hard, compact, brilliant, and quite resonant, looking not unlike Connellsville coke. It is in large pieces, one lump being over three feet long. Unfortunately, no analyses of it are given.

These important coal-fields run entirely across the State in a direction about northeast by north, in a band from some twenty-five to forty-five miles wide, with a total area of 5100 square miles, containing from one to seven workable seams. The eastern edge of this field is from fifty to sixty-five miles from the North Carolina frontier. The main seam, the one which yields at present the greatest amount of coal, is called the Sewanee, and has an average thickness of 4 feet 6 inches, its greatest thickness being reported at 10 feet 4 inches, and its smallest at two feet.

The largest coal mining operations are carried on by the Tennessee Coal, Iron, and Railroad Company, which does extensive work at Tracy City, where it has 600 ovens, besides having coal mines and coke-ovens at Victoria. The output of coal for the State is stated to have been 600,000 gross tons in 1880, 750,000 in 1881, and 850,000 in 1882. In J. D. Weeks's census report, it is stated that coke was made in four establishments in 1880, with a capital of $200,021, employing 144 hands, to whom were paid $38,820 in wages, consuming 179,311 net tons of coal, worth $124,137 and $8092 worth of other materials, producing 91,675 net tons of coke, worth $212,493. This represents a yield of 50·9 per cent of coke from 100 of coal, and a profit of $41,444, or upward of 20 per cent on the capital represented, or about 45 cents per ton of coke.

From these figures, we may deduce the cost of making a ton of coke as follows:

COST OF PRODUCING ONE TON OF COKE IN TENNESSEE.

Material.	Quantity.	Rate.	Amount.
Coal	1·89 tons.	$0.69 per ton.	$1.37
Miscellaneous	...	...	0.09
Days' labor	0·5	$0.82 per ton.	0.42
Total cost			$1.88
Profit per ton			0.45
Value of one ton of coke			$2.33

Making a similar calculation on Mr. Weeks's figures for the Pennsylvania coke production for the year ended May 31st, 1880, we arrive at the following:

COST OF PRODUCING ONE TON OF COKE IN PENNSYLVANIA.

Material.	Quantity.	Rate.	Amount.
Coal	1·56 tons.	$0.56 per ton.	$0.87
Miscellaneous	....	.....	0.09
Days' labor	0·38	$1.11 per ton.	0.42
Total cost of one ton of coke			$1.38
Profit per ton			0.43
Value of one ton			$1.81

The figures here given for the rate of wages and the number of days' work per ton of coke are inaccurate, being based on the assumption that each hand worked 365 days. They give, however, a rough idea of the state of things.

The following analyses, taken from Macfarlane's *Coal-Fields*, give a rough idea of the character of the greater part of the Tennessee coal:

County.	Place.	Analyst.	Fixed carbon.	Volatile.	Ash.
Grundy	Sewanee mine.	Stewart.	63·50	29·9	6·6
Hamilton	Chattanooga.	T. S. Hunt.	63·90	26·8	9·3
"	Salt Creek.	Stewart.	56·75	40·7	2·5

Iron Ores.—The iron deposits of the State may be conveniently grouped into three geographical districts: The East Tennessee, comprising a narrow strip adjoining the eastern boundary, in the northeastern part of which a considerable quantity of charcoal pig-iron and of blooms have been made; the Cumberland Mountain region, extending from near Chattanooga (near the southern border and considerably to the east of its center) to Hancock and Claiborne counties on the northern border, immediately adjoining the eastern side of the coal-field, and running parallel with it; and the Western Tennessee region, forty miles wide, running north and south, in which considerable charcoal pig-iron is made in four counties, from three hot-blast and three cold-blast furnaces.

The Cumberland Mountain region includes Chattanooga and South Pittsburg, the rolling-mills and the seven coke-furnaces of the State.

The ores now mined are the fossil red hematite, locally called dyestone in the Eastern and Cumberland regions, and limonites in the West Tennessee region. The Eastern region also contains beds of dense, hard hematites and of beautiful compact crystalline magnetites like those of Lake Champlain and of the Cranberry ore-bed in North Carolina, which closely adjoins them. These ores are all exhibited; but it is stated that the magnetites and compact hematites have not yet been mined to any considerable extent. They occur in the extreme northeastern part of the State.

Several very extensive and workable beds of siderite (spathic iron ore) are said to accompany the coal-beds, which have not yet been worked.

The following statistics of the pig-iron manufacture are on the authority of Mr. J. M. Swank:

Year.	1872.	1876.	1881.	1882.
Charcoal pig, tons	43,094	10,068	19,046	37,611
Coke pig, tons	3,360	14,517	68,360	99,991
Total	47,454	24,585	87,406	137,602

The increase in the output of coke iron was to be expected, but the rapid decrease of the charcoal pig make from 1871 to 1876 seemed to

Digitized by Google

threaten its extinction; yet it has rallied, and in 1882 actually stood higher than in 1872. The following figures are from the same author:

IRON AND STEEL PRODUCED IN TENNESSEE IN 1882.

	Net tons.
Pig-iron	137,602
Rolled iron, including iron rails and rail plates	38,770
Iron rails	19,610
Steel rails	5,780
Steel ingots and other crude steel	4,000
Blooms from pig and scrap-iron and iron ore	700
Bar, rod, hoop, skelp, and shaped iron and iron axles	10,589
Cut nails, 171,413 kegs	8,571

Zinc Ores and Spelter.—Messrs. Edes, Mixter & Heald here exhibit their zinc ores and metallic zinc in slabs, and rolled down and sheared across the grain, to show its strength. No figures of the zinc industry are given, but we learn from the Compendium of the Census of 1880 that, in that year, 3699 tons of zinc ore were mined in Tennessee.

Marbles and Building-Stones.—Those who were at the Centennial Exhibition will not be surprised to learn that Tennessee makes a very telling display of most beautiful polished marbles. They are mostly of the familiar red and white mottled kind, reminding one somewhat of Castile soap, as a fair sister may remind you of an ugly one. There are also many beautiful drab and dove-colored marbles. Among the localities represented by particularly beautiful marbles may be mentioned Indian Camp Spring, in Maury County, which has several different kinds; Charleston, which has a very striking "green peanut" marble, so-called; and Chattanooga and Knoxville. They are all surpassed by a most brilliantly mirror-like slab from Red Triangle (at least it is called "Red Triangle marble"). The Tennessee marbles are extensively sent to New York and even to Boston. Those who have visited the new capitol at Albany must have been charmed with the beautiful marbles from this State, of which the governor's room is built.

The principal seat of the marble industry is in Hawkins and Knox counties, in the Eastern and Northeastern parts of the State. For the year ended June 30th, 1881, there were shipped over the East Tennessee, Virginia & Georgia Railroad about 3,651,000 pounds of marble from Hawkins County, and above 10,000,000 pounds from Knox County, and it is estimated that some 80,000 cubic feet of this stone are annually sent out of the State. In the census year, thirteen quarries of marble and other stones were worked with a capital of $131,700, producing 792,621 cubic feet of stone worth $192,695. From the Crescent marble of Knoxville, comes a very beautiful white marble shaft, thirteen feet high, and apparently entirely free from flaws. Each of the four sides is finished in a different way, to illustrate the different effects which can be readily produced. It is stated that this company can furnish shafts one hundred and fifty feet long without a flaw.

The Missouri Pacific Railroad sends a great number of galena and other ores from Arkansas; but, as is too generally the case with displays of ores, no ready way is offered of acquiring valuable and trustworthy information about them. A very beautiful and close-grained novaculite, deliciously white, tells its own story as regards its quality; but its quantity and the manner of its occurrence are left to the imagination of the beholder.

Here I may remark that it seems strange that mine-owners and managers, railroad and land companies, and others who take great pains and spend considerable money in sending ores to public exhibitions, should not go to the slight additional trouble of adding to their displays the few statements which are needed to enable them to convey any important information to the visitor. It does one little good to know that Arkansas has galena, that Arizona has malachite, that Greenland has cryolite: what the visitor wants to know is, in general, the commercial importance of the deposits, and this could be clearly conveyed to his mind by a few simple statements. He wants to know how much galena the State, the region, or the particular mine in question has; how rich it is in silver; how deep the mines have gone so far; how near they are to transportation; what is the nature and size of the deposits; are they pockets, gash-veins, fissure-veins, stockwerk? what is the composition? if a smelting ore, what fuel is available, and at what price? etc. Even if all this information can not in every case be given, in most cases some information can be; and going to the trouble of displaying minerals without taking the little additional pains needed to make that display effective, seems to me like erecting a town-clock, but omitting the hands.

Pyrolusite from Polk County, Arkansas, is exhibited, stated to be from the largest deposit of this mineral in the world. The evidence on this point is hardly overwhelming, and it should be received with a pinch of the beautiful salt which is (perhaps for this purpose) conveniently exhibited near by.

About the beautiful woods here exhibited from Arkansas there need, however, be no difference of opinion. Both in their variety and in their beauty, they are indeed bewildering. Many of them take a very high polish, and not a few are of very great value from their intrinsic merits apart from their beauty. Among those which particularly charm the eye may be mentioned the black cherry, the live-oak, the ailantus, the iron-wood, and the mesquite. The latter two are of especial interest to those of us who have vainly endeavored to shield ourselves from the shriveling sun of Arizona and New Mexico, in what would be their shadow, if they had any, and have cursed their nakedness.

Texas Products.—The same railroad, the Missouri Pacific, also exhibits some very handsome woods from Texas, which vie with those from Arkansas and North Carolina in beauty. The pecan and live-oak struck me as especially attractive, as is also the finely-polished, deep-hued red cedar, as beautiful as mahogany, and not unlike it. From the same State, are also displayed a number of valuable and finely-polished building-stones, granites, both red and gray, with a fine sheen, and many others. A very handsome dove-colored marble, with an exceedingly fine grain and an excellent polish, deserves great admiration.

We are informed of the existence of the refractory material industry in this distant State by some fire-bricks made by the Fire-Brick and Tile Company, of Kosse. Their appearance is creditable, but no analyses or other data are furnished to enable one to judge of their merits.

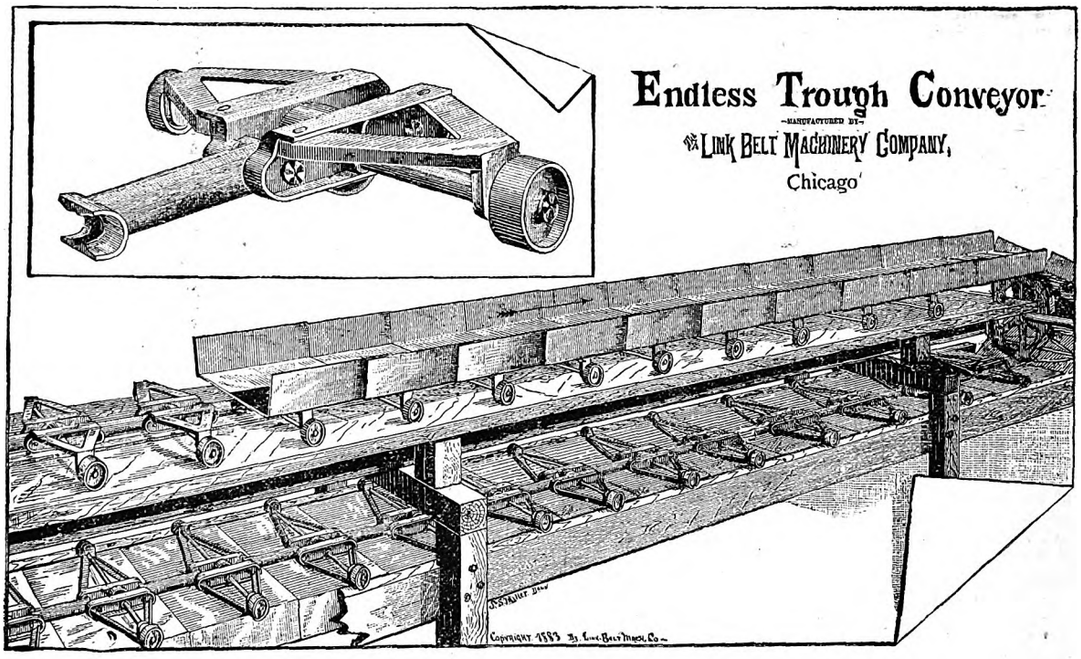
The Union Pacific Railroad has an extensive display of minerals, but, as in the case of the Missouri Pacific, there is no cooling draught of statistics to slake the visitor's parching thirst for accurate information. Many and beautiful agates there are, and what are attractively labeled "crystallized trees." With dendritic crystallizations of another kind we are already familiar. There is also quite a display of cabinet minerals and of fossil fishes, said to come from the Yellowstone Park.

Of the Northern Pacific Railroad display, much the same must be said. There are many and various ores of copper, gold, silver, and lead; but whether epresenting minute or gigantic deposits we are not told. From the Bismarck Artificial Stone Company, of Bismarck, Dakota, come several fine-looking tiles, blocks of artificial stone, fire-bricks, etc. The tiles are in excellent taste, well executed, and altogether most commendable, and they indicate a state of progress in this industry which is highly creditable to this distant city.

The Canadian Pacific Railroad exhibits some handsome, lustrous, pure-looking bituminous coal from the coal-fields west of Manitoba; they are just across the Canadian line from Montana, and immediately east of the main chain of the Rocky Mountains. Four mines are now worked in this Canadian coal-field, supplying the railroad and local consumption. Considering how lately the road has reached their neighborhood, and that the first of these mines was opened this summer, this speaks well for the future of coal mining here. Gold quartz is also exhibited from a number of gold mines which are said to be actively worked in the Lake of the Woods District, among them those of the Argyle Gold Mining Company, the Winnipeg Consolidated Gold Mining Company, and several others.

Rhode Island Granite.—From the Smith Granite Company, come some beautiful pieces of very fine granite work, made from the famous granite of Westerley, Rhode Island. Many of the designs are very beautiful, and the highest praise is deserved both for their workmanship and for the material itself, some of which is worked into shapes none too easy to attain even with the finest statuary marble. In a handsome life-size statue made from this granite, even the nails are beautifully, delicately, and truthfully cut, showing a fineness of grain, uniformity, and trustworthiness not often seen in a material so coarse and so treacherously flaky and cleavable as granite.

Connellsville Coke.—It may seem like carrying coals (or cokes) to Newcastle to tell your readers much about this famous product; but I fancy that comparatively few of them know to what an extent it is already replacing anthracite even in the New England foundries, which are so very much nearer to the anthracite than to the coke region. But here we have the Frick coke from Connellsville, in our Exhibition, triumphantly telling us that a very considerable proportion of our most intelligent foundrymen already pay allegiance to it, and that with the others it is simply a question of a little time. No less than eight important foundries in Boston and its suburbs now use it, and such important and ably-managed concerns as the Bridgeport Malleable Iron Company, Tuttle & Whittemore, of Naugatuck, the Pratt & Whitney Company, J. B. & J. M. Cornell, and the Barnum-Richardson Company, of Lime Rock, are large consumers of it. Most of these concerns consider that some thirty per cent more iron can be melted with a pound of coke than with one of anthracite, the best regular practice being from 6 to 6·5 pounds of iron per pound of anthracite, and from 8 to 9 pounds per pound of coke. The low melting duty in foundries, compared with that of the Bessemer works, is due mainly to the large proportion which the bed in foundry work bears to the total charge of coke. It is also generally admitted that a much lighter blast is required, in itself no small advantage, and that coke melts much more rapidly than anthracite, as is also the case in iron blast-furnaces and in lead and copper smelting cupolas. Some intelligent founders consider that it does not take more than two thirds as long to melt with coke as with anthracite. Finally, some concerns which are so situated that coke costs as much as anthracite per unit of melting capacity, prefer it on the ground that it makes much softer castings. This point is not so well established as the others, and probably only certain grades of iron or certain classes of castings are softer when made with coke than when anthracite is employed. In some foundries, anthracite is used for the bed and coke for the rest of the heat. To sum up, the advantages claimed for coke over anthracite for foundry purposes are: 1. A duty 30 per cent higher than anthracite. 2. A rate of smelting from 30 to 50 per cent higher than that of anthracite. 3. A less powerful blast is needed. 4. The castings are softer. This is not clearly established.



Asbestos.—Of the many interesting applications of asbestos exhibited by the H. W. Johns Manufacturing Company, I should have considerable to say had you not already lately discoursed at length on its uses on page 228 of the present volume. Still a few words must be said: First, we have many different and agreeable colors of wholly fire-proof paint, made without oil, and said to contain only completely oxidized and hence absolutely incombustible substances. Certain it is that it is incombustible in the ordinary sense of the word. Next, we have several sizes and kinds of packing, some large, some small. The fine twine packing for small valves is especially attractive and soft, and appears wholly free from grit, as its reputation leads us to believe that it is. Next, we have the unwrought asbestos fiber, which looks as soft and fleecy as eider-down; nor is one disappointed in its softness on submitting it to the ordeal by touch. Then there is the mill-board, as it is called, which is like pasteboard in appearance and feeling, except that it is tougher and does not peel into layers. This is shown of many thicknesses, the thinnest being hardly thicker than ordinary Irish linen or other heavy linen writing-paper. This is extensively used for making joints, being unaffected by heat, moisture, and by scarcely any chemicals. The asbestos employed comes almost wholly from Canada, where it occurs abundantly, frequently associated with serpentine. It is of comparatively short fiber, say from three to four inches long, compact, and of a dark green, and is very unlike the beautiful white, long-fibered mineral from Italy, there so common that Dolomieu packed his minerals with it. One would think that the compulsory use of asbestos paint, or some other form of really fire-proof paint, in such wooden cities as San Francisco and Leadville, would considerably diminish the now very serious danger of an uncontrollable and exterminating fire, such as swept wooden Chicago. H.

SALE OF NORTH CAROLINA LAND.—The State sold on October 31st 30,000 acres of land known as the Big Swamp, situated in Robeson County, on the Carolina Central Railroad, to O. H. Blocker, of North Carolina, and George S. White and W. N. Jennings, of Pennsylvania, for 27½ cents an acre.

AN ENDLESS TROUGH CONVEYER.

The endless trough conveyer is one of the latest applications of link-belting, consisting primarily of a heavy chain belt carried over a pair of wheels, and in the intermediate space a track on which the chain runs. This chain or belt is provided with pans, which, as they overlap, form an endless trough. Power being applied to revolve one of the wheels, the whole belt is thereby set in motion and at once becomes an endless trough conveyer. The accompanying engraving illustrates a section of this conveyer. A few of the pans are removed, to show the construction of the links; and above this, a link and coupler are shown on a larger scale. As will be seen, this link is provided with wings, to form a rigid support for the pan to be riveted to it. To reduce friction, each link is provided with three rollers, as will be seen in the engraving. This outfit makes a fire-proof conveyer which will handle hot ore from roasting-kilns to crusher, and convey coal, broken stone, or other gritty and coarse material. The Link-Belt Machinery Company, of Chicago, is now erecting for Mr. Charles E. Coffin, of Muirkirk, Md., about 450 feet of this conveyer, which is to carry the hot roasted iron ore from the kilns on an incline of about one foot in twelve up to the crusher. This dispenses with the barrow-men, and at an expenditure of a few more horse-power becomes a faithful servant, ready for work in all weather and at all times of day or night. This company also manufactures ore elevators of any capacity, which, used in connection with this apparatus, will handle perfectly any thing in the shape of coarse, gritty material. It might be added that the endless trough conveyer is no experiment. Although comparatively new in this country, it has been in successful operation for some time in England, the English manufacturers of link-belting having had great success with it.

AMONG THE IRON WORKERS.—STEELTON.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: A few miles from Harrisburg is an establishment of some note in industrial matters. It is the works of the Pennsylvania Steel Company. The locality was formerly known as Baldwin's station, but has recently been changed to the highly appropriate name of Steelton. Here it is that many of the thousands of steel rails that are annually produced first take their shape. The Doctor and I had seen the sights of Lebanon pretty thoroughly, and decided to start for Harrisburg in the early train that leaves at six o'clock; but in this we were disappointed; for as the awakening knock came only eight minutes before train time, we could scarcely hope, in spite of our recognized activity, to dress, pack up, and breakfast, while the clock ticked out its four hundred and eighty seconds. Being somewhat philosophic, we spared ourselves any vain regrets about the matter, and coolly prepared for the next train, leaving about half-past eight. Though the distance down to Steelton is so short, yet it was not till nearly twelve that we reached the place, and introduced ourselves to one of the blast-furnace draftsmen. It is a very pleasant feature to record of these various establishments that the inquiring stranger is treated most cordially, and the employés put themselves to almost any trouble that their visitors may see and hear to their full content. We found our guides very attentive and intelligent gentlemen. The works, even if one visits them unattended, are absorbingly interesting; but the pleasure of our examination was chiefly due to the kindness and intelligence with which all the various processes were pointed out and described. Though by this time we had seen much of blast-furnaces in other parts of the State, yet we found a great deal to interest us in the drafting-room at Steelton. Two large furnaces were in course of erection at the time of our visit, and the designs were of the latest pattern. But the parts which most claimed our attention were in connection with the steel production. Neither of us had ever seen the operation, and it was with mingled admiration and wonder that we gazed upon the huge Bessemer converters, and watched the apparently easy transformation of the pig-iron into the more useful steel. It takes a stranger some little time to accustom himself to the noise and glare of the Bessemer apparatus, and to really examine the process thoroughly. The attendant appearances and phenomena are so striking in their character that they divert the attention from the truly essential points in the process. In company with the manager, we picked our way over the heaps of old iron and *débris* that invariably accompany an iron establishment, and having gained our destination, a large gloomy-looking building, we entered, and applied ourselves to learn the secrets of the Bessemer invention. It was a strange sight that met our eyes: showers of sparks, great volumes of flame, and clouds of steam combined to rival the most brilliant pyrotechnic display, while the large and still red-hot ingots of steel, the diminutive locomotives, the numbers of attendant men and boys seemed mixed together in utter confusion. But the disorder is only apparent; for under all there run the most perfect order and discipline. And, indeed, it is most essential that it should be so; for any confusion and failure in one of the numerous details of the process would bring delay and disaster upon the whole. The huge Bessemer converter, made of iron, and lined with fire-clay, is, at Steelton, capable of treating ten tons at a time. It is mounted on massive iron trunnions, so that it may be turned on its side at pleasure when filling with the liquid pig-iron, or when, at the end of the process, the resulting steel is run out into the large iron molds waiting to receive it. The whole process is intensely interesting, and it is one that has succeeded only after many struggles with practical difficulties. All honor to Bessemer, Kelly, Holley, and the other brave spirits who, in the face of so many obstacles, have achieved such grand results! We will follow the metal in its course from the state of pig-iron to that of steel. In the upper portion of the building, and at a level above the converters, there is a series of small blast-furnaces arranged in convenient position. These "cupolas" serve to melt the pig-iron and spiegel, and thus prepare it for its introduction into the converters. These, red-hot and glowing, are turned on their side and are ready for the charge of metal. The clay-lined channel that leads into these capacious mouths brings down the molten iron from the cupolas above. The bottom of the converter is slightly contracted, so that the bulge of the vessel when turned on its side is sufficient to contain the molten pig-iron and keep it below the level of the perforations in the bottom. These tuyeres admit the air-blast that is to burn out the silicon and carbon, and thus convert the iron into steel. The blast having been turned on, the recumbent vessel, with its molten contents, is raised to a vertical position, and the transformation begins. As the converter slowly swings to its upright place, the air-blast carries minute particles of iron out into the air, and these oxidizing, produce showers of innumerable sparks. It is an exhibition of great beauty, and in an age more superstitious than our own would not inappropriately be considered as the breath of the iron genii. The vessel having been righted, the twelve-minute "blow" begins. The flame that first issues from the mouth of the converter and rushes noiselessly up the chimneys is small and compact, though intensely hot: it is the burning silicon. But gradually the flame increases in volume and brilliancy; it lightens up the entire building in spite of the rivalry of the sunlight: the carbon is now consuming. Formerly, the various stages of the Bessemer flame were watched and studied by means of the spectroscope, an instrument which analyzed the flame, and revealed the spectrum of the burning elements. Practice, however, has now made the workmen so proficient in determining the end of the process that the spectroscope is but seldom employed. The carbon flame gradually increases in intensity, reaches its hight, and gradually diminishes. When the volume becomes quite small, thus indicating that the greater part of the carbon has been consumed, the flame shows the brownish appearance of burning iron. The process is now ended, and the converter is again turned on its side. As the blast must not be removed until the metal is below the level of the tuyeres, the blow ends with a second grand shower of sparks, and the breath of the genii vanishes. As the blast of air has removed the greater part of the carbon, the metal remaining in the con-

Digitized by Google

verter must be partially recarburized. This is accomplished by adding a certain percentage of spiegeleisen. The resulting steel is then poured out into a large ladle, and from this is distributed into the ingot molds. As soon as the metal becomes at all chilled, a stream of cold water is poured into the top of the mold, and the ingots cooled off as rapidly as possible. The water, coming in contact with the red-hot metal, is at once converted into steam. As the large clouds rise from the casting-pit, obscuring the workmen and all the apparatus, they form an effective pedestal to the vast volume of flame that is belching forth from the mouth of the again active converter. It is a very impressive sight, and, once seen, can scarcely be forgotten. There was much to interest us at the immense works; but we had arranged to go to Altoona in the evening, so after a hasty glimpse at the bloomaries and machine-shops, we bade our kind guides farewell, and boarded the western-bound train. Mrs. Stowe begins *Old-Town Folks* with the apology that even the most commonplace life, if faithfully recorded, affords ample material for an elaborate romance, and in like manner, the modern traveler might find his excuse for long letters in the fact that the most ordinary journey is crowded with many incidents, amusing or pathetic as the case may be. It is our misfortune, when traveling on the Pennsylvania Railroad, almost invariably to be detained from some cause or other; and on the few hours' ride that separates Harrisburg from Altoona. we lost about two hours from a freight smash-up which had occurred so recently that the wreck still encumbered the roadway. We were obliged, in consequence, to run on the left-hand or eastern-bound track, and the necessity caused a very sad accident. One of the company's trackmen, as he trudged over his dreary round, was struck by the locomotive and thrown aside. When the train backed to the spot, we found that death had been more rapid than we, and we could only carry the poor dead body back to its home. The man had probably heard the warning whistle, but being so confident that the train was on the other track, he had entirely disregarded it, and hence the accident. It caused a momentary gloom to settle over the passengers, but what the sensations of the engineer were at the time of the contact we hardly cared to imagine. The delay and the accident together made the travelers inclined to be neighborly. The little drummer in the seat ahead of us was particularly irrepressible. He began with the weather and matters in general, but it was not long before he drifted to the subject evidently the nearest to bis heart—his intended visit to his *fiancée*. He had not seen her for some four or five months, and he was evidently too full of the subject to remain silent, so he favored us with his confidence and even showed us her photograph; but the half twilight that pervaded the car gave us little opportunity to judge of the beauty of one whom "he thought more of than he did of himself"—to chronicle the intensity of his devotion in his own words. CARL.

INVESTMENTS IN MEXICAN MINES.

Special Correspondence of the Engineering and Mining Journal.

The current of speculation has for several years past set violently toward Mexico; but unless the mysterious laws which seem to regulate finance be revised, the tide will ebb as strongly as it has flowed. The result, as it affects mining, will be a suspension of the most legitimate projects, as unreasonable as has been the crazy confidence with which money has been thrust upon the dishonest and ignorant promoters of the most extravagant delusions. It is not to be wondered at that Mexican mining schemes should receive support, appealing so forcibly as they do to the imagination of the purchaser, and affording, as they believe, such unlimited scope for the play of imagination on the part of the seller. Mexico has produced $3,000,000,000 of silver, and still pours forth $30,000,000 annually. The inference that mere common sense might draw from the first figures would be that, in the nature of things, there must be little eft in store whence so much has been taken; but the second figures contradict this conclusion. Nevertheless, as preference is given to the one ine of argument or the other, will capital be refused or granted for the more important and costly mining claims.

The enormous output of the past affords undoubtedly, when coupled with the large output of the present, proof positive that the wealth which Mexico inclosed within her mountain ranges is by no means exhausted; but it does not necessarily prove that the old mines whence this wealth was extracted will pay if rehabilitated. Some perhaps will, some certainly will not. The history of the last days of some, if it reached the ears of the investor, would determine him to keep his money in his pocket. The facts ascertainable about the closing scene of others make it justifiable to risk heavily in reopening them; but the same romantic story is told in almost every case of rich ores, which the imperfect Mexican method failed to beneficiate, but from which Yankee machinery will extract their full value; of revolutions which depopulated the region, and therefore closed the mines; of water which flooded them in the face of the puny appliance with which the Mexicans fought it; of rich workings closed because devils haunted them or priests cursed them, and so on and so on.

It is unquestionably true that mining was often checked, and some good mines closed, as one of the baneful results of revolutions; it is equally true that the horse-whim failed to cope with the water; and that in many cases good mines could not find capital to pay for steam-pumps. But it is not true that Mexican metallurgical methods are both costly and defective, and that all old mines were killed by external violence rather than by internal disease.

What is too generally true is, that an unscrupulous man, with ready wit and a glib tongue, goes south to Mexico, either denounces abandoned mines or buys an old languishing one for a trifle, concocts his romantic tale, and sells the history and the mine in the North for as many hundreds as he expended units. What follows is perhaps the necessary corrollary of the first act of folly. As the valuable mine was abandoned because its ores would not yield to Mexican treatment, therefore American treatment must be applied, and a mill built; but as amalgamation failed, in the Mexican *patio* process, therefore leaching must surely be the thing, and accordingly a roasting-furnace and tubs are put up. Skill to conduct the operation is the last thing thought of. Already the cost has far exceeded the estimates, and economy must be practiced, and as usual, economy at this point means cheap management. A director of a Mexican company boasted how admirably they saved the salary of a metallurgist. They had employed a man at a figure high in their estimation. He was taken mortally ill on his way South, and arrived at the mine a doomed man; but during the few remaining days of life, the superintendent tortured him into imparting all he knew, and that so effectually that, when death released his victim, the inquisitor felt himself to be a fully equipped metallurgist and competent to run the leaching-works. How the leaching-works succeeded need not be told. A clever fellow christened Parral the Leadville of Mexico. The misnomer created a smelting plant big enough to reduce in one day all the lead ores Parral could produce in a twelvemonth. But whoever lost the money, the epigram-writer probably did not. A still cleverer man discovered, by *a priori* reasoning, the existence of tin in Durango some centuries after it had been worked. He described a course through Cornwall, Queensland, and Penang, and, projecting it across the American continent, the line struck Oregon. His subsequent application of the experimental method in Oregon showed no tin there. So he revised his chart, and the curve fell on the Conito tin-field of Durango. Perhaps, after all, his first iso-stannic line was the correct one; for had he continued it across the continent, it might have led him to the tin-field of the Black Hills and Alabama. Such charlatanism is not confined to Mexico; yet it seems to be most seductive when practiced on minds already predisposed to believe the marvelous, as most people are when they invest in foreign mines.

The records of the great mines of Mexico are matters of history. The condition of some of those mines below water-level is only matter of tradition. To put into working order such mines as Sombrete and Fresnillo, will admittedly cost hundreds of thousands of dollars. Those who decide to resuscitate these great enterprises do so with full knowledge of the facts and of the risk they run. They know the fate which befell so many similar enterprises in the hands of Englishmen, sometimes through palpable mismanagement, at others through the poverty of the mines; but they count in their favor the accessibility which railroads will give to their property, and the salutary effect of closer supervision on their superintendents, and they depend for dividends on the cheapness with which the railroad enables them to equip their mine and mill with efficient machinery. We admire the courage of these adventurers, and every one interested in mining wishes them the rich reward they deserve. But no sympathy is due to the sufferer who has eagerly swallowed the fly decorated by some promoter with ridiculously gaudy feathers. Correct and honest information is within the reach of every investor, if he is willing to pay for it. He only offers a premium to dishonesty by investing his money without inquiry. Of this he may be pretty sure, that, as the Mexican is a good miner and a good metallurgist, if he abandons a small shallow mine, his doing so affords strong presumptive evidence of its worthlessness. The Mexican does not conduct his underground operations on the same system, and does not break down ore from large veins as cheaply and with as little damage to the mines as we do; but he can trace with unerring instinct the course of the rich ore, and he removes only what it will pay him to treat. There may be some profit in mining and milling his leavings; but the profit will generally be scanty. Another fallacy which enters the stock in trade of a Mexican promoter is, that we can always make profit out of ores which the Mexican, with his clumsy methods of treatment, has to reject. In certain localities, this is true; but it is by no means always so. At points near the railroads, we can undoubtedly smelt lead and copper ores with coke more cheaply than he can in his little furnaces, so expensive in labor and fuel. But we must recollect that heretofore labor has been one third or one quarter cheaper than it will hereafter be in the vicinity of the railroads, and this will go far to reduce the advantages which cheap freights will give us. But it is questionable whether in localities where fuel and water are scarce ore mill processes and machinery will reduce free silver ores more economically and with less loss than the *patio*. It is of course inapplicable to very base ores, and, in handling these, a leaching process may in some cases be preferable to amalgamation after a chloridizing roast, or to the usual Mexican method of fusion with lead ores and litharge. But it is unwise to start with the assumption that Mexican methods are crude and inefficient, and that we can of course make money where they, in their ignorance and unskillfulness, failed. It is also hardly necesary to contradict the ridiculous stories of the richness of the ores. There is everywhere very rich ore, confined to very small veins or bunches. The average of very large bodies is comparatively low. J. D., JR.

MINING MATTERS IN CHIHUAHUA.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Though mining in New York appears to be sleeping "the sleep that knows no waking," we are far enough distant to be out of reach of the soporific influences that attach to the business there. Although we are by no means under the influence of a boom at present, yet there is a lively interest evinced in all mining matters, which is well sustained by such events as the arrival, on the 14th ult., of the monthly "conducta" from Batopilas with 100 bars of silver. This was the result of twenty-seven days' work, and is the largest conducta ever sent out from that district.

There are a numer of Americans in the city at present, and foreign capital is slowly but surely taking hold in this State. I say slowly, not merely on account of the lagging in business transactions peculiar to the country, but from a variety of other causes, chief among which may be counted the fact that a demand for an article increases its value ten, even a hundred, fold in a Mexican's eyes, and especially now, since the influx of Americans, when many think they have but to ask in order to receive. The unfortunate affair at Pinos Altos, the killing of Mr. Hepburn, the manager there, last winter, is said in one case to have deterred English capital from taking hold; while others disposed to invest wait first to see the success of the principal railroad schemes, knowing the importance of their bearing toward mining. Therefore, our progress is slow, but undoubtedly as sure as slow, and the caution engendered is a most desirable and beneficial factor in placing mining here on the solid basis it occupies, and in promising it a certain and greater measure of success.

While there are but few mines in the immediate vicinity of Chihua-

Digitized by Google

hua, the fact that the city is the railroad center has made it also the mining center for all but the most northwestern and southern districts of the State. From Pinos Altos to Batopilas and Urique, bullion is sent in for coinage and shipment to the United States, while from the east outputs may be looked for in a reasonable time, as American companies have recently been formed to work the Guadalupe gold placers of the Conchas River, and the Santa Domingo galena and carbonate ores of the same district, which are similar in formation to the Santa Eulalia ores here; that is, pocket or chamber deposits in limestone. These Santa Eulalia mines, situated about nine miles east of Chihuahua, are about reaching a successful stage of operations, and keep eight 4½-ton wagons busy daily carrying ore to the mill. Two miles east of the city, on the south bank of the river, this latter is situated, and it has but just been put in operation, every thing working most admirably. Built by Fraser & Chalmers, the mill consists of 20 stamps, 24 wooden settling-tanks, 12 pans, and 6 settlers, with buddle and Frue vanner for concentration of slimes. A 250 horse-power condensing-engine from the Kensington Works, Philadelphia, drives the mill, and lifts the ore up an inclined plane to the crusher above the stamps. A retort and melting-room and an assay-office are erecting adjoining the mill, and the plant will shortly be in full working order. At Cosihuiriachic, two days' ride east of Chihuahua, the new Howell-White roasting-furnace has at last been set to chlorinating successfully under the direction of Mr. Riotte, and the leaching-works are now giving a steady output. The ore, gray copper, galena, and pyrites, is produced entirely from the San Bartolo shaft, now over 600 feet deep, being hoisted in a half-ton Cornish kibble. The rich smelting ore is sorted for shipment to New York, while the lower grade, averaging about 60 ounces, is crushed under 20 stamps, chlorinated and leached, the roasted precipitate being also shipped.

In the more western districts, work is pushed in quite as energetic and successful a manner. At Pinos Altos, 45 stamps are busy, and report puts the mine in a most satisfactory condition, while the bullion shipments arrive regularly, consigned to Norwald & Co., of this city.

At Yoquivo, the San Francisco and Pertenencia mines, yielding chlorides and native silver, are worked to but a small proportion of their capacity by 15 stamps with Hendey concentrators. The mines are very promising, and it is probable will change hands before long.

The Carmen & Batosagichic Company, at Guazapares, has recently taken hold of a property there consisting of thirteen mines, of which the principal ones are the Carmen, San Miguel, and Santa Clara. The company is about to enlarge its 20-stamp mill, having put a steam hoist in the Carmen mine, now 300 feet deep, and bought up the old Santa Clara mill, which was erected some years ago and fitted with 24 barrels, for barrel amalgamation. A small cupola-furnace enables it to make use of the old iron for mill castings, and work is rapidly pushed under the direction of Joseph McNulty, E.M.

Twenty miles west of Guazapares, at Palmarejo, a new California mill of ten stamps, with pans and vanners, has just been erected, for the treatment of ores holding principally chlorides, and is working side by side with the old Mexican arrastra mill, which is also kept busy. At Santa Rita, one half-mile below Guazapares, there is a five-stamp mill and small leaching-works; and at Uruapa another, while from here the high-grade ores are shipped to the coast and to Germany.

In Cententrion, there are large deposits of low-grade ores, at present worked by arrastras run by water-power, but an American company is negotiating for their possession, intending to work them on a large scale, there being an abundance of wood and of water-power, and the town lying on the route of the projected Texas, Topolovampo & Pacific Railroad.

Farther to the south, lies Batopilas, and this district at present rather leads the rest in the output of silver. This output is obtained just now entirely from the small mill of 15 450-pound stamps used for crushing the rich first and second-class ores only. The large mill is undergoing repairs and being doubled in capacity by the addition of 15 more stamps, alongside of the others. These take the ore directly from the cars run down from the San Miguel mine, nearly a mile up the river. This ore is low grade, consisting of zinc-blende and galena, with occasional specks of native and black silver in a gangue of spar and dioritic greenstone, and is concentrated on twelve Frue vanners, the headings, assaying from 220 to 300 ounces, being panned, while the tailings, which never assay over five ounces and seldom above three, are run into the river. The settled slimes from all the pan amalgamation, whether from headings or rich native silver ore from the small mill, are roasted and lixiviated by the hyposulphite of lime process.

Two "Fortschaufelungs-Ofen," undoubtedly the cheapest roasting-furnace for these districts, chlorinate the ore for this latter process, the plant for which is yet small, consisting of eight 15-ton leaching vats, three precipitation-tanks, with necessary filter and pump-tanks. The past week, there were received at the Hacienda of San Miguel over eight tons of first-class ore produced from the San Miguel and other mines under Governor Shepherd's management; and first-class ore assays anywhere from $2000 to $10,000 per ton, seldom under the former figure. The mines giving the greatest amount of rich native silver at present are the San Miguel, Camuchin, Roncesvalles, and Ballinas. The tunnel of the former mine, nearly 1400 feet long, cuts 13 large veins, and the principal of these, which have already given large bonanzas of silver, though still holding simply immense areas of unexplored contents, are the Mesquite, Veta Grande, Carmen, and San Antonio.

The vein of San Antonio de los Tachos of the Camuchin Silver Mining Company's property has given rich silver since last June, when communication was established between the tunnel, 700 feet long, and the air-shaft, 340 feet deep, and the mine put into workable shape.

The Ballinas air-shaft, 280 feet deep, the deepest vertical shaft in the district, has also been connected with the old tunnel, 780 feet long; and in Roncesvalles, the lower tunnel, 536 feet long, with the upper one, 150 feet above it, a continuous product of native silver being obtained from this mine, beginning almost with the first blast put in it.

But a detailed account of the several good mining properties of Batopilas would take far too much of your space, on which I have already trespassed.

I would speak of one more district in good production before closing, and that is Urique, forty miles west of Batopilas, where the Becerra Brothers have struck an ore-body at a depth of little more than 500 feet in their Rosario mine, that has yielded largely the past year, and continues the entire width of the vein, six feet between walls. The ore is a very rich galena and tetrahedrite, flaked often with native silver, and is crushed under 15 stamps and smelted and cupelled in six Mexican "vasos," that is, adobe cupel furnaces.

T. H. L.

CHIHUAHUA, MEXICO, Oct. 2.

THE LAW AS AFFECTING MINING AND METALLURGICAL INTERESTS.

A Knotty Coal Case.—The case of Kerr and Fowler and Carleton, claimants for coal land in Wyoming, in which case the points of both the secretary and commissioner were published in this journal when made, having come before the commissioner again in another shape, his last decision has sufficient points of interest to warrant a pretty full statement of the case. Kerr and Fowler appealed from the decision of the local officers at Evanston, refusing to allow them to purchase and enter certain coal lands, the first having made application upon his own D. S., and the latter as assignee of James Buzzo's D. S. In the former contest, the following facts were developed: December 19th, 1881, George W. Carleton applied to purchase and enter the land covered by his coal D. S. Kerr and Fowler, among others, contested his application at a hearing which was decided in favor of Carleton. Upon appeal to the General Land-Office, the decision of the register and receiver was affirmed. Upon appeal to the secretary, the commissioner's decision was modified as follows: It was held that Carleton was not, at the date of his application to complete his entry, in occupation and possession of the land covered by his coal D. S.; that he had, by the operation of a bond entered into with the Utah-Wyoming Improvement Company, transferred all his interest in said land to that company, and was therefore not entitled to patent. "If, however," said the secretary, "the Utah-Wyoming Improvement Company can show its right to prove up and purchase as assignees of Carleton, it will be permitted to do so." January 5th, 1883, Kerr and Fowler applied to purchase, claiming that, as the application of Carleton had been rejected, "there remained of record in the land-office at Evanston only the coal D. Ss. of the appellants, which remain intact, as they have not been canceled by the Hon. Secretary of the Interior, as it is not asserted that the appellants had failed to comply with the law.' The commissioner, in his present decision, says he does not regard the view taken by the appellants as correct. "It was decided by this office, from the evidence presented, that Carleton, by reason of the character and amount of his improvements, was entitled to enter the land embraced in his coal D. S. instead of Kerr and Fowler. This finding of *fact* was not disturbed by the Hon. Secretary; but he decided, as a matter of *law*, that Carleton's assignees, and not Carleton himself, were *entitled* to make entry upon filing the necessary proofs. This being the case, the register and receiver properly refused to allow the appellants to enter the land. The D. S. of Carleton not having been canceled, entry by any other party could only have been allowed after notice to him. The only effect would have been to inaugurate another contest upon the merits of the case, between the same parties or their privies, involving the same matters of fact which had been already decided. The claims of Kerr and Fowler, therefore, as against Carleton and his assignees, were *res adjudicata*, and could not be revived. Moreover, I do not consider that the decision of the Hon. Secretary of December 11th, 1882, relegated the Utah-Wyoming Improvement Company to the position of one who holds, under a coal D. S., but has not yet applied to make entry. If the decision of this office had been affirmed *in toto*, Carleton would have had the right to purchase and enter the land without further objection, upon filing the necessary proof. The decision of December 11th, 1882, merely substituted the company for Carleton, and his status became theirs in all respects. His application to purchase, and the decision of the resulting contest, inured to their benefit. There was, therefore, on January 5th, 1883, a prior application to purchase, which was an appropriation of the ground embraced therein, until finally disposed of. And the applications of the appellants were, on this ground, rightfully rejected. The appeals of Kerr and Fowler are therefore dismissed."

The application of the applicants having been rejected, the Utah-Wyoming Improvement Company was allowed on January 16th, 1883, to enter and purchase as assignee of Carleton; and the commissioner proceeds to say "that the register and receiver erred in allowing this entry. Their action in rejecting the applications did not become final until the thirty days allowed for appeal had expired. The record shows that within such thirty days, namely, on January 27th, 1883, said Kerr and Fowler did appeal to this office, which appeal has just been considered. Inasmuch, however, as the appeal has been dismissed, and as the applicants have no standing before this office as parties in interest, since a decision adverse to their rights has been rendered by the Hon. Secretary, the entry will not be canceled on that ground, but will be allowed to proceed upon its merits. Coal entry No. 11 being allowed to the said Utah-Wyoming Improvement Company, the appellants appear in the character of protestants, and ask the cancellation of the entry on two grounds: First, that the company has not shown its right to purchase as assignees of Carleton; and second, that it is disqualified to purchase under the law and regulations of this office. Second. The records of the office show that one Charles M. Gilberson filed in the land-office at Salt Lake City, Utah, coal D. S. No. 342 (same section), January 21st, 1882, and that the latter filing is now a matter of contest in this office, upon appeal from the decision of the register and receiver in favor of said Gilberson. The sworn statement of Franklin Barnard, Secretary of the Utah-Wyoming Improvement Company, shows that Charles M. Gilberson was a stockholder in said company from May 7th, 1881, to June 15th, 1882. John W. Kerr, one of the protestants, makes affidavit that the above parties are one and the same person. The Utah-Wyoming Improvement Company files no formal proof of an assignment to it by Carleton. It is evident, therefore, that they rely upon the decision of the Hon. Secretary, declaring the bond given by Carleton to be in fact an assignment. That bond was executed on December 20th, 1881, as shown by a copy thereof certified to by the clerk of Uinta County, Wyoming. That date must, therefore, be held to be the date of the assignment under which the company claims. From December 20th, 1881, then, until June 15th, 1882, the company had among its members a person who was disquali-

Digitized by Google

fied to claim coal land under the laws providing for its disposal. Counsel for protestants claim that this disqualification attached to the corporate association itself under the regulations, and Section 2350 Revised Statutes. The record shows, however, that the said Gilberson sold his stock on June 15th, 1882, and that entry was not made until January 16th, 1883. It has not been shown that any of the stockholders at the date of entry were disqualified. I can not accept the protestants' construction of the law and regulations. The Hon. Secretary affirmed the validity of Carleton's claim, and the rights of the company are their rights under Carleton. The land is therefore held by Carleton's original claim or filing, and not primarily by direct claim of the company. The disqualification of a stockholder in the company while the land was so held could not affect the validity of the claim. I must, therefore, decline to hold the entry for cancellation on that ground, as requested by the protestants. The evidence, in my opinion, fails to show the disqualification of two other stockholders of the company, E. H. Murray and H. A. Van Proag, as alleged by protestants, nor has the identity of the Utah-Wyoming Improvement Company with the Black Diamond Coal and Coke Company been satisfactorily established. The proof filed by the company in support of its claim is, however, deficient in several particulars. No affidavit of the individual members of the company at date of entry affords the information required by official regulations. The claimant is required to file additional proof covering these points.

Parties Interested in Application for Patent.—"A" made application for patent, and the abstract of title developed the fact that he was not the sole owner of the claim, and the local officers were notified and called upon to show why the other parties interested should not be joined with the claimant when patent issued. Such call is always the practice in the General Land-Office under similar circumstances. In reply, it was stated that the names of the other parties had been inadvertently omitted. Under the circular of July 6th, 1883, a patent can not issue for the interests of other parties in such cases, because they are not applicants nor assignees of applicants for patent. This is in accordance with a decision of the secretary in the case of the Grampian Silver Mining Company. But although parties in interest are ignored by the applicant for patent, and, filing no adverse claim to assert their rights, have waived them by failure to file such adverse claim, still those rights are not a subject for consideration by the General Land-Office in passing upon the regularity of the proceedings by the claimant in the case; and while he is in this instance unable to comply with the office regulations in showing exclusive right of possession, and, by former decisions, the entry must be held for cancellation, still the case comes under the secretary's decision that, "if antecedent publication and attendant proceedings have been regular, all that might have been set up by suit in court has been adjudicated in favor of the applicant." This so perfects the title that "A" will obtain patent if the application is regular in all other respects. Again, if "A" files a written statement that the parties were excluded inadvertently, patent will issue to them, together with "A," upon final proof of the claim.

The Right to Open Mines in School Sections.—The General Land-Office, in reply to a recent query made as to the right to open mines in sections reserved for school purposes in the States and territories, replies affirmatively. The Hon. Carl Schurz, while Secretary of the Interior, settled this question, in so far as Dakota was concerned, when called upon to determine the right of the United States to bring an action for trespass upon Sections 16 and 36 of public lands reserved in Dakota by Congress for the use of schools. He said: "The lands are public lands, although reserved for a particular purpose. The United States has not granted the title to such lands, but has reserved them, in order that, at some future time when a State shall be erected out of such territory, the same may be granted to such State."

The Supreme Court of the United States, in the case of the Mining Company *vs.* Consolidated Mining Company, held that a grant of public lands to the State of California by the act of March 3d, 1853, for school purposes, "was not intended to cover mineral lands, but such lands were excluded from that grant, as they were from all others, by the settled policy of the government on that subject." The operative words of the California act are, "shall be and hereby are granted," and there was no question raised as to the intent of Congress to grant to the State of California the lands, other than mineral, therein specified. The department says now: "It appears settled that it was never the intention of Congress to grant to a State or territory any mineral lands for school purposes, and it follows *a fortiori* that it can not be presumed to have been its intention to *reserve* any portion of them to be applied in the future to such purposes. It is proper to remark further, that, since in case of the lands in question the United States never parted with its title, it was entirely competent for Congress to exclude the mineral portion thereof (even conceding that a reservation of the same land had been made) from such reservation, by the mining act of July 4th, 1866." This construction of the act is also in keeping with that of Secretary Delano, in the Keystone case, which issues afterward came up to the Supreme Court in the Mining Company *vs.* Consolidated Mining Company, and in keeping with the judgment of the court therein.

The case just considered by the department is a coal land entry from Utah. The act of September 9th, 1850, to establish a government for that territory, says: "When the lands in said territory shall be surveyed under the direction of the government of the United States, preparatory to bringing the same into market, sections numbered sixteen and thirty-six in each township in said territory shall be, and the same are, reserved for the purpose of being applied to schools in said territory and in the States and territories hereafter to be erected out of the same."

FURNACE, MILL AND FACTORY.

The Boston & Colorado Smelting Company, of Argo, Colorado, has placed an additional order for roller chain belting with the Lechner Manufacturing Company, Columbus, O. This company has also received orders for chain belting from the Yazoo City Oil-Works, Yazoo City, Mich., for propelling steamboats. In addition to the above, it has furnished the following firms with tan-bark conveyors: W. W. Kellet & Co., W. Hickory, Pa.; D. Gensemer & Co., Pine Grove, Pa.; Francis Hammond, Coudersport, Pa.; and others.

The Cummer Engine Company, of Cleveland, O., has opened a branch office at 34 South Canal street, Chicago, under the management of W. B. Pearson.

The North Chicago Rolling-Mill Company's mill, at South Chicago, was the scene of a terrible explosion about eight o'clock on the evening of the 21st, which fortunately resulted in no loss of life. It being Sunday night, no work was doing in that locality, otherwise the loss of life would certainly have been great. The tunnel leading from the gas-house to the rail-mill, built of brick, exploded, sending masses of brick and mortar in all directions. The tunnel was eight feet in diameter, and was destroyed, as well as the ceiling overhead. As soon as the *débris* was cleared away, fifty masons were at once set to work, who completed the repairs Monday night.

The Catasauqua *Dispatch* says: Messrs. Crump & Berden, of Philadelphia, have had manufactured at the Union Foundry and Machine-Works, this place, an ingenious machine for cutting slate, marble, granite, and other materials. One just completed has been placed in use near Siegfried's Bridge, and is working very satisfactorily. An immense saw revolves with lightning speed and slits the slate, and saves the labor of many workmen. It is also used in sawing slabs for pavements, mantels, etc. The Union Foundry and Machine Company has a large planer in course of construction for the patentees. It has orders for two more sawing-machines, and prospects for numerous other orders from the same parties.

An explosion occurred at half-past one on the 19th ult., at Blast-Furnace No. 2, of the Pennsylvania Steel Company, Steelton, Pa., which shook the houses for squares around. The breast of the furnace was entirely blown out, and the molten metal flowed around promiscuously.

In a week or ten days, the barb wire mill and galvanizing building, erected along the canal in South Easton by the Iowa Barb Wire Company, will be ready for service. The main building is a frame structure, 45 feet wide, 260 feet long, and two stories in hight. Some of the machinery for this part of the works has already arrived. The upper story will be used for manufacturing the barbed wire. The lower story will be a machine and manufacturing room. The galvanizing building is also a frame structure, 40 by 80 feet. This building is also nearly completed. Another building, which will be used for painting wire that will not be galvanized, is now in course of erection. It is said that the average product of the works will be 4500 tons a year.

At the Vulcan Boiler-Works, of James McPeil & Brother, Pittsburg, a battery of boilers has been made for the Pittsburg Manufacturing Company. A large battery has been made by this firm for the Pullman Iron and Steel Company at Chicago, and also a 400 horse-power engine.

At the Atlas Works, Pittsburg, a pair of large blooming-shears are now making for the Edgar Thomson Steel-Works. The bed-plate of it will weigh 32 tons, and is the heaviest casting ever made at these works. They are also making an ax poll machine for Hubbard, Bakewell & Co., a hoisting-machine for Graff, Bennett & Co., and one for the Pittsburg Steel and Casting Company. They are also making a complete plant for manufacturing glass bath-tubs, including all the machinery, hydraulic accumulator, presses, and a great variety of other machinery.

At the Keystone Boiler-Works, W. Manchester, proprietor, Pittsburg, the manufacture of steel anvils will be again started.

A Pittsburg firm has leased the Pennsylvania Furnace, located on the line of the Lewisburg Central & Tyrone Railroad, in Franklin township, from W. Lyons & Co., the owners, and will put it in operation as soon as the necessary supplies of material can be obtained. This furnace has been idle for more than six years.

With the exception of one or two departments, the mills of the Mahoning Valley Iron Company are on full-time.

Mr. June Dunbar, foreman of the machine-shop of Brown, Bonnell & Co., has invented a self-feeding nail machine which he has just patented. In construction it is much less complicated than other machines.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY—TOMBSTONE DISTRICT.

BLUE JACKET.—It is rumored that extensive work in this mine will be soon resumed.

CONTENTION.—Rapid progress is made in placing the pumping machinery. It will probably be in working order by the first of December.

GIRARD.—Since the mine started up, a month ago, the ore output, although only ten men are at work, has amounted in value to somewhat over $3000. The mine is more than self-supporting. The lower levels show a large body of sulphuret ore containing a large percentage of zinc. The Benson smelter not being able to handle such refractory ore, it has so far been useless to extract it; but arrangements have been made with the Pueblo (Colo.) Smelting and Refining Company, for the treatment of the ore.

GRAND CENTRAL.—Nearly all the work done is in the upper levels. The 200-foot level is worked the most extensively at present. There is hardly any ground above the water-level that is not prospected. Sinking will be resumed as soon as the pumps have started.

INGERSOLL.—The mine has been leased and work will be commenced soon. Although the ore is very refractory, carrying a large percentage of zinc, it contains enough silver to bear shipment to Colorado, should local smelting-works be unable to handle it.

TOMBSTONE MINING AND MILLING COMPANY.—A small force of men is employed on the Good Enough ground, mining some very high-grade chloride ore. The workings on this claim are mostly very near the surface, the ore being taken out wherever it shows itself, without doing much prospecting for it. The company's main workings are on the West Side, where a depth of 450 feet has been attained. At Charleston, the company has just completed the erection of four new concentrators. The flux used at the furnace is manganese ore derived from the Lucky Cuss and Luck Sure mines. As it carries from 40 to 50 ounces of silver to the ton, it is by far the best and cheapest flux that could be obtained.

PIMA COUNTY.

ESPERANZA.—The mill is almost completed.

FRANCO-AMERICAN.—A rich strike has been made. A test-run of 20 tons of the ore will be made by the Orion mill.

ORION.—The mill is working successfully on ore from the Mountain mine, belonging to this company.

PINAL COUNTY.

RAY COPPER.—For the week ended October 21st, the superintendent reports: Our last week's working in the Ray continued to show very favorably. Winze No. 3 from station 100-foot level is down 19 feet, carrying glance ore. Have started to drift from station, 100-foot level, west, to cut the native copper deposit we had above. This drift is now in five feet from station and in native copper, the same body we had in winze No. 1 and north drift 50-foot level. The cross-cut in the south drift in front of winze No. 3 is in 48 feet; the face is in copper glance. Cross-cut, north drift, 50-foot level, is in 35 feet; the face is in red oxide, copper glance, and fine native copper. The cross-cut in tunnel level

Digitized by Google

is in 25 feet, and also looks well in red oxide and copper glance, one seam in the face being very rich indeed. Shaft No. 1—a shaft sunk outside of all former workings and 50 feet from the mouth of the tunnel—is down 15 feet. We intend to do all our hoisting through this shaft, and the same will be connected with the 50 and the 100-foot levels as soon as possible. We have a steam hoist now on the road from Tucson to put up over this shaft. I expect now to be able to put 4000 tons of ore on the new dump.

CALIFORNIA.

INYO COUNTY.

ARGUS RANGE SILVER MINING COMPANY.—Thirty tons of ore produced 137 ounces of bullion, worth about $2200. The mill is now shut down for want of water. It is stated that the company will soon place enough funds at the disposal of the superintendent to pay off all indebtedness.

CHRYSOPOLIS.—The machinery for a five-stamp mill is on the road, and will be put in place as soon as the work is enough advanced.

SAN DIEGO COUNTY—POOR MAN'S DISTRICT.

This comparatively new district was discovered in 1864, and worked in a small way for galena. The mines were abandoned, however, and in 1881 contractors began assessment-work on the Luz mine. Re-location of the abandoned claims was made, and in 1882 other claims were located.

AMELIA.—This claim has been opened to a depth of 180 feet by shaft on the foot-wall, showing ore from the surface and at intervals to the floor of the shaft, from which level a cross-cut of 40 feet has been run, tapping the hanging-wall. The chloride streak, four feet in width, is here uncovered, and chloride of the green horn-silver variety found in quantity. From the surface, a shaft, now at a depth of 40 feet, is pushed on the hanging-wall, to connect with the 180-foot cross-cut, and the rock extracted is pay-ore. Negotiations are pending for the purchase of this mine by California capitalists.

SAND-STORM.—A strike has been made in two feet of solid argentiferous galena, white and yellow carbonate. Chloride also is found on this location, as also on the Nameless, the extension of the Sand-Storm.

CANADA.

PROVINCE OF NEW BRUNSWICK.

BELLIVEAU ALBERT.—Borings recently have reached a depth of 680 feet. As the operations have proceeded, oil has been met with at times. It is stated that the flow of oil is continuous. The oil is remarkably pure.

COLORADO.

The United States Central Railroad Company, organized under the laws of Colorado, has filed articles of incorporation. The capital stock is $75,000,000, divided into 750,000 shares of the par value of $100 each. The time of the commencement of the company dates from the 1st day of October, 1883, and the company is to continue fifty years. The object is the construction of a railroad from Denver across the State of Colorado, the territory of Utah, and the States of Nevada and California to the city and county of San Francisco, in the latter State. The incorporators are A. D. Sharon, R. H. Floy, Charles Kohler, Lyman Bridges, D. L. Randolph, W. L. French, M. Skelley, Frances Bridges, J. P. Manrow, Sampson Tams, Samuel McCullough, J. Bluxome, Robert Turner, Samuel Grove, H. H. Pearson, San Francisco; E. T. Wells, William C. Miller, and Edward Rundall, Denver; and William Walker, Cedar Rapids, Iowa. There will be a meeting of the directors in San Francisco soon, at which time the officers will be elected. As soon as the organization is effected, a survey in Colorado will be made, and then work will be begun at both ends of the road.

ARAPAHOE COUNTY.

INTERNATIONAL PYRITES SMELTING COMPANY.—This company has filed articles of incorporation which define the purposes of the company to be to carry on in the State of Colorado and elsewhere the business of amalgamating, treating, and refining precious metals. The capital stock of the company is fixed at $500,000, divided into 20,000 shares, and the following are named as directors: Homer Pennock, Dennis Sullivan, James V. Dexter, George H. Corbin, and Edward O. Wolcott. The place of business of the company will be in Denver.

CLEAR CREEK COUNTY.

CASHIER.—This mine, at Empire, has lately been examined in the interest of Chicago capitalists. Reports were so favorable that forfeit money was paid down and the Chicago parties allowed the privilege of sinking a shaft on the lode.

COLORADO CENTRAL.—The mine is looking well. Several new ore-bodies are opening up. A large amount of dead-work has been done on this property, and exploration has reached the west end of the claim. In No. 2 level, west from the engine-shaft, a new and apparently rich ore-body has been encountered.

DOLORES COUNTY—RICO.

Mr. Linwood O. Towne, of Rico, sends us the following notes:

GRAND VIEW.—The company is working the usual force of men on its mine, obtaining ore mainly from the Phœnix and Grand View. The large furnace at the smelter has been recently blown in, about 300 tons of ore being on hand at the time. These have been and are being obtained not alone from Rico mines proper, but also from Ophir and Mount Wilson.

SOUTH PARK.—The usual force is working. Recent shipments of lots to Grand View Smelter gave the following results: Silver, 410, 122, 225, and 990 ounces, and lead on same 30, 11, 20, and 14 per cent, respectively.

CROSS.—Shipments to the smelter during the month past were 60 tons, running from 72 to 220 ounces of silver, and from 8 to 25 per cent lead. This mine has lain idle a long time, but the owners are now pushing things, employing from 15 to 20 men.

NEWMAN GROUP.—The company owning this group, which includes the Newman, Swansea, Chestnut, etc., started work early in October, running day and night shifts. At present, the mines are being put into good shape by extensive development-work; they have not been worked except by lease for over a year, during which time a large quantity of high-grade mineral was taken out. The practical superintendence of the mine is under Mr. F. W. Reed, a former lessee. Mr. A. B. Burnham, manager, is in town giving the business of the mine his personal attention.

LITTLE MAGGIE.—Upward of 75 tons have recently been shipped to the smelter. Work is pushed mainly on the tunnel.

INTRA MUROS.—An offer has been made by this company on the Little Pittsburg claim, and if the purchase is concluded, the mine will be worked extensively in connection with other properties owned by the company in the same vicinity. The claim is developed by a tunnel 300 feet long and a shaft at 225 feet in, 22 feet deep on the Aztec Gulch side of Expectation Mountain. From the opposite side, another tunnel is run 100 feet and a shaft is sunk 40 feet. The 300-foot tunnel is in lime and porphyry all the way. Properties already owned by the company are the Mohegan, Blue Bird, and Stranger. The first-named has a cross-cut tunnel 160 feet and a drift on the vein of 134 feet, showing a large vein of carbonate ore.

GILPIN COUNTY.

FRONTENAC.—A lease of this mine, more familiarly known as the Clifton, has been taken by Dr. Henry Paul, who has ten miners at work in developing and opening up new ground. This vein is situated near the head of the south fork of Willis Gulch, Russell District, and heretofore has been worked quite extensively.

GUNNISON COUNTY.

BONANZA.—This group of mines, consisting of the Bonanza, Amie, Little Eva, Ground Hog, and Bonanza No. 2, situated on the southeast side of Gold Hill, in Quartz Creek Mining District, was sold for the sum of $70,000. The Bonanza and Amie are patented claims. They were located in 1879, and have a large amount of development. Recently, a large body of high-grade carbonate ore was struck in the Bonanza.

JEFFERSON COUNTY.

MINERS' SMELTING AND REDUCTION-WORKS.—It is pretty thoroughly understood in Golden that these works have been sold to the Boston & Colorado Smelting Company, of Argo, and in all probability will soon be closed.

LAKE COUNTY.

ADLAIDE.—The lessee who recently took charge of the property has directed his attention to more thoroughly opening the mine and extending exploration work into new ground. In consequence, although from 28 to 30 men have been continually employed, the production of the mine has been small. Operations are carried on through both the Ward and Adlaide No. 2 shafts.

AMIE.—The northern portion of this mine, and also the workings contiguous to the No. 2 shaft, are worked by the company with encouraging results. The northern workings disclose fair indications of a good body of ore, and some good shipping mineral is obtained from them. Shipping ore is also extracted from the No. 2 shaft. Shafts Nos. 4 and 1 are worked on royalty. So far, however, the lessees have taken out very little, nearly ten months of work having yielded only about one thousand dollars. The Deer Lodge shaft is worked on a lease, and while producing some ore, has so far failed to disclose a bonanza.

ARGENT.—The increased production of the Vining mine is the result of several new developments recently made, giving the mine extensive resources in sight, as well as ore-bodies that promise great permanence. The shipments of the mine are sorted into two classes, the first netting about thirty dollars per ton above smelting charges, while the second class ranges from eighteen to twenty dollars. The principal ore-body of the mine is to the southwest of the shaft. The present developments show a breast of ore twenty feet in width, eight feet in hight on an average, and open for a distance of thirty feet.

CHRYSOLITE.—Carbonate and galena ore has been found in the Muldoon shaft, located on the southern portion of the Chrysolite property. The mineral was encountered at a depth of 140 feet. The shaft is worked on a lease. The new strike, if equal to expectations, opens up a new field for prospecting. It is quite likely that the ore-body developed recently in the Luzerne shaft is connected with this ore-body, in which event the four or six hundred feet of intervening ground will contain some very respectable bonanzas. If the ore-body is really a large one, it will improve the chances of both the Little Pittsburg and Chrysolite mines.

CLIMAX.—Shafts Nos. 1, 3, 6, and 7 are working under leases with varying results. No. 1 shaft so far is the only one that has yielded any quantity of ore and more than paid expenses.

COLONEL SELLERS.—A contract for a year has been made with the Harrison Reduction-Works, to take 750 tons of ore a month. The operations at the mine are confined to exploration-work. The sinking of the No. 2 shaft is still in progress, although it has passed through fifty feet of ore. The Accident shaft is also pushing down at a rapid rate, and has attained a depth of 170 feet. Levels are also extending and prospect-drifts driving in various directions.

IRON SILVER.—The No. 5 shaft of the Stone claim is producing about 40 tons of ore a day. No. 6 shaft on the same location is turning out about 160 tons a day, making a total daily production for the California Gulch mines of the Iron Silver Company of two hundred tons. The Moyer shaft is closed down entirely, pending the receipt of a new pump. The surface improvements of the company are nearly completed. Exploration-work is still in progress from the McKeon shaft, driven on the line of the fault from the Iron mine incline. The workings show several fair streaks of ore, and the value of the product is equal to the expenses.

OPULENT.—The suit of the Opulent and Australian lodes, involving conflicting territory, has been decided in favor of the Opulent mine. The case was tried in the United States Circuit Court at Denver, and the jury was out nearly three days before arriving at an agreement.

RUBY.—The principal developments of this consist of a main west level, 345 feet in length, in which good ore has just been struck. At 295 feet west of the shaft, and about forty feet above the plane of the main level, there is an ore-body, the mineral of which consists of gray sand carbonates ranging from 40 to 65 per cent in lead, and from fifteen ounces upward. The ore-body, as far as developed, discloses a thickness ten feet and over, a width of about fifteen feet, and a length of forty feet, with fine ore in the breasts on three sides. At a distance of 100 feet west of the shaft, an incline has been driven to the southward on the contact, showing in the face a fine breast of mineral four feet in thickness, from which the principal output of the mine is at present secured. In a drift running to the northwestward, 65 feet from the shaft, a natural cave has been opened 30 feet deep, 70 feet long, and 15 feet wide, the bottom of which is covered with ore running fifteen ounces to the ton.

TWIN LAKES PLACER MINING COMPANY.—A large force is employed on the Clear Creek ditch, of which about 5000 feet have so far been completed. Of the flume grade, 16,000 feet, or nearly the entire length, has been finished. A contract has also been let for driving a tunnel, of which about 500 feet have been run up to the present time. The entire work is advancing as rapidly as practical, and will be completed in season for work in the spring. No changes have been made in the line and none is contemplated.

PARK COUNTY.

EAST LEADVILLE.—This company, which has recently purchased the Mudsill and other mines in Horse Shoe Gulch, has put a force of fifteen at work on its property. The company contemplates erecting a stamp-mill early next spring. The ore possesses value of from 25 to 30 ounces in silver to the ton.

LONDON.—The mine is producing regularly, and the flue twenty-stamp mill of the company is kept running at its full capacity. Unless the deep snows of that section should interfere with the operation of the railroad, the mine and mill will continue turning out gold bullion and high-grade concentrates during the entire winter. The mine is looking well, and the resources and available stoping ground are daily increasing, notwithstanding that regular shipments have been made for months past.

DAKOTA.

A dispatch from Fargo states that a mining company with a capital of $500,000 has been formed by leading citizens of that place, and a claim has been filed for 200 acres of the town-site of Lisbon. Work will be prosecuted vigorously on the arrival of machinery, which has already been ordered.

CLIMAX.—The shaft at this mica mine has attained a depth of 90 feet. At present, seven men are at work in the mine, and produce nearly 200 pounds of cut mica per week.

FATHER DE SMET.—The superintendent writes: Ore extracted from first, second, and third levels, 1885 tons. Ore milled, 1975 tons. Golden Gate east cross-cut, third level, advanced 5 feet; Golden Gate south header, second level, advanced 6 feet. Under date of October 18th, he reports: I herewith inclose express company's receipt for bar No. 169, containing 748·70 ounces of gold, the result of run of mill for the first half of October. At the mine, every thing seems to be looking as favorable as usual, and we see nothing to prevent us making fair shipments all winter, and at a reduced rate of expenses, as we have a full supply of every thing in the material line on hand, and nearly paid for. Golden Gate south header shows no change; in fact, for the last 65 feet, the quality has not varied at all, and if the ledge proves to be of any size, will make a very fine chamber. East cross-cut, third level, does not look so promising. The face is in ledge-matter yet, but of scarcely no value. The rest of the mine

Digitized by Google

shows the usual amount and quality of ore. The mill continues to work well, and gives no trouble.

HOMESTAKE.—A rich strike, it is said, has been made in the Old Abe shaft, which has attained a depth of 450 feet. At present, the workings are 135 feet only from a level with Whitewood. The shaft is in ore of good quality almost the entire distance, but for the last 100 feet it has steadily increased in richness, until, at a depth of 440 feet, the workings entered a body of ore, the general character of which is far superior to any thing heretofore encountered. The shaft will be sunk to a depth of 550 feet.

ORO FINO.—It is stated that the superintendent has received from his company ample means to liquidate all indebtedness; consequently, there will be no cessation of work in mine or mill.

ROCHFORD.—Eastern capitalists, it is said, have a two-years lease of mine and mill, with the privilege of buying at the expiration of that time for $175,000.

UNCLE SAM.—The 25-stamp mill continues in successful operation on an excellent quality of ore. A 60-stamp mill will probably be erected next year.

GEORGIA.

LUMPKIN COUNTY.—During the present season, says the Dahlonega *Signal*, there have been erected in this district something over 100 stamps, and 20 more are now to be added to the number already in the field. Prospectors have been busy, and new territory is constantly added to that worked and known to contain gold in paying quantities. Negotiations are now in progress for the purchase of a considerable tract of mining territory, by a company of Northern capitalists, which, if completed, will add greatly to the prosperity of this section.

SINGLETON.—Developments in the tunnel are of a favorable character. The vein at this point is three feet thick, and prospects well. A force is at work stoping the ore. A railroad has been laid from the stopes to the mill, and self-dumping cars convey the ore directly to the feeders.

IDAHO.

ELKHORN.—The new developments have placed in sight bodies of high-grade galena in the breast of tunnel No. 1, in the stope between tunnels 1 and 2, in winzes Nos. 2 and 3, and in rises Nos. 1 and 2 for the winzes. This shows a large continuous body of first-class ore. The average net receipts for every ton of first-class ore shipped to the Philadelphia smelters are said to be $165. This is after the deduction of transportation and reduction. Besides a regular daily shipment of 12 tons of ore, much is done to give the mine a complete drainage by means of a tunnel from the east hillside, which will tap the vein at a depth of 500 feet. This will also be the main working tunnel.

STAR.—The new strike made in this mine, in Star Gulch, within two miles of Hailey, consists of three streaks of ore. One of these is four inches wide, of gray copper and galena, which assays high in silver. The drift is in 20 feet on the new find, which seems to improve as run upon.

MEXICO.

SCHLEY MINING AND MILLING COMPANY.—This company owns seven splendid mines near Pachuca, the Ida, Robert E. Lee, Washington, New York, La Reina, Savannah No. 1, Savannah No. 2. Of these mines, the Ida, La Reina, Robert E. Lee, and both Savannahs are in good honest paying ore, and these ores are not in pockets, but in true fissure-veins, which, when worked on a large scale, will pay bonanza profits to the stockholders. All that is now wanting in this district is a first-class reduction-mill, as the ores have to be shipped eighteen miles to be reduced.

MICHIGAN.

The following table exhibits, in gross tons, the total lake shipments of iron ore from upper peninsula ports the present season, up to and including October 24th, together with the amount shipped from the same ports during the corresponding period of last year:

Name of port	1882.	1883
Escanaba	1,579,846	1,281,885
Marquette	846,240	628,101
L'Anse	60,780	59,395
St. Ignace	49,062	48,078
Total	2,535,928	2,017,459

EMMET.—The shaft which is sinking on the tract adjoining the Ludington, where it is expected to strike the Chapin vein, is down 140 feet. The shaft, it is believed, will strike the Chapin vein at a depth of about 600 feet.

ERIE.—It is rumored that this mine has been sold to Cincinnati capitalists.

FINLAND.—Articles of incorporation were recently filed at Lansing. The capital stock is $2,125,000.

GREAT WESTERN.—A small force is now worked, getting the mine in shape for economical production.

PEWABIC.—Another assesment has been levied. The superintendent says: It seems to me the best thing we can do is to sink another lift, then push along the 33d and 34th levels north and south, to prove up the ground that we are gaining from Franklin and Quincy. With Quincy rich on one side, and Franklin showing well on the other, our chances for finding some good paying ground, if the openings are pushed along as stated above, are very good indeed; and if we do not make some good bunches of copper long before this time next year, it will be very strange. There is nothing new at the mines.

WEST CHAPIN.—Indications point to the early development of a workable deposit of first-class ore.

MONTANA.

MISSOULA COUNTY.

The first reports received from the gold-fields in the Cœur d'Alene Mountains were greatly exaggerated. The latest information is, that the prospects will not justify any great excitement, but that there will be paying diggings. Some 220 or 300 people are in the camp. Most of the claims, comprising twenty acres each, have been taken by Palouse farmers, and very few miners have secured ground. The ground on Beaver Creek and other streams in the vicinity of Pritchard Creek has been taken up; but the work of development will be very slow this winter, and paying returns may not be expected before next July. As yet, but four claims have paid any thing, and none of them at present makes more than wages. One party sold part of a claim, five acres, for $1000. The neighborhood has every indication of being a good quartz region, and a couple of ledges have already been opened on Beaver Creek, six miles from Pritchard Creek.

SILVER BOW COUNTY—SUMMIT VALLEY DISTRICT.

ALICE.—The pay-chute has been struck and stoping begun on the 800-foot level. The width of the ore-body at present is three feet, averaging 57 ounces, and is increasing in width. The vein at a point 130 feet west from the bottom of the winze is 47 feet wide. The south vein is opening up on the 400-foot level east of the main shaft. On the 300-foot, stoping is vigorously prosecuted on the new south vein. The ore-body is extending east and west, and is rich, averaging 100 ounces. The foundations for the new hoist on the Magna Charta mine are finished, and the new engines will be set, the old engines being much too light for the service required of them. The mills are running very regularly, and crush 100 tons per day.

BLUE WING.—This claim has been leased on the following terms: The lessee is to have all the ore taken out in sinking and drifting, and four fifths of that taken out in stoping.

GOLD FLINT.—A two-thirds interest in this mine was sold to W. A. Clark for $13,000. This mine lies two miles west of the Moulton, and is the outlying mine westward on this mineral belt. The ore is high-grade. One shaft is down 90 feet and another 60 feet, both in good ore.

LIQUIDATOR.—Active developments have begun again, and about 100 tons of first, second, and third-class ore are produced daily. The first-class averages 35 per cent of copper; the second-class averages 27; the third class, 18. Most of this heavy production is left on the dump, but regular shipments have recently been made; and since July 1st, the sum of $36,000 has been realized from the sale of crude ore on the dump, and which has been shipped to Swansea under contract to New York parties. The amount previously realized from the sale of first-class ore only was $8000. A conservative estimate of the amount of third-class ore on the dump at present is 7000 tons, the sale of which has been arranged for. There is also a considerable amount of second-class ore on hand. Under the new schedule of freight rates, the superintendent states that 26 per cent ore, which a year ago would not pay to ship, is now available for transportation even as far as Swansea, and pays a profit above all costs. The Liquidator is not a full claim, being only about 650 feet long, but like a good many other fractional claims in this district, according to the Butte *Inter-Mountain*, it is one of the most productive and valuable properties in the camp.

MOULTON.—The 400-foot level is driving west, and has greatly improved in the character of the ore. The battery samples are from 100 to 125 ounces. This body of ore is about five feet wide in the stopes.

NEVADA.

ELKO COUNTY.

ELKO CONSOLIDATED.—Depth of shaft No. 2, 170 feet. There has been a favorable change in the formation, it now being porphyrite, and carrying small stringers of ore.

GRAND PRIZE.—The prospects are said to be very encouraging. The mill will start up on the 5th of next month.

ESMERALDA COUNTY.

COLUMBUS CONSOLIDATED.—The extraction of ore has been resumed.

HOLMES VS. NORTHERN BELLE.—Some of the lawyers and witnesses in the Northern Belle suit are beginning to arrive in Carson. The suit is brought by the Holmes Mining Company to recover the value of ore, estimated to be worth $1,000,000, taken out of ground claimed by the Holmes Company. It is alleged that the Northern Belle people went over their end boundary-lines in taking the ore. The case will be called on the 6th of November, and will bring about one hundred jurors to the city.

MOUNT DIABLO.—The drift below lower winze No. 2 shows a strong ledge, which is turning out some $45 quartz. The stope from this winze is yielding considerable $55 ore. The stope below the third level, and near winze No. 1, shows a strong ledge of $50 ore. The cross-cut running directly south of the shaft is extending to prospect the ground below, to ascertain the depth of the Tipton ledge.

EUREKA COUNTY.

EUREKA TUNNEL.—The committee appointed to report on the general and financial condition of the company states that the present indebtedness, as it appears on the books, is $51,719. It advises the stockholders to contribute fifty cents a share, for the purpose of liquidating the indebtedness and starting the company on a clear and sound basis. The money may be sent to Paxton & Co., bankers, at Eureka.

STOREY COUNTY.

KENTUCK.—This is the only mine in Gold Hill which did not shut down this season on account of the low water in the Carson River, and the consequent stoppage of the mills.

NEW MEXICO.

BERNALILLO COUNTY.

There is a movement on foot to establish a Mining Exchange in Albuquerque and this movement is regarded as one of more than ordinary importance.

Charles L. Hubbs has transferred to Frank Huning *et al.*, all his right, title, and interest in and to the smelter property below Albuquerque. It is understood that some move will be made in the near future to put the works in active operation.

A party of prospectors have recently discovered in Tyeras Cañon, about sixteen miles east of Albuquerque, a gold lead which gives promise of being rich and extensive. The lead runs nearly north and south, and crosses the cañon about three miles from the mouth. The vein has an iron cap, some ten or twelve feet in thickness; and after going through this, an ore-body is struck which carries gold from the start, and steadily improves as depth is gained.

DONA ANA COUNTY.

SIERRA BELLA.—It is reported that the Columbia mine, at Lake Valley, has been sold at auction to the Sierra Bella Company for $30,500. The Sierra Bella Company owned two thirds and Hon. John D. Miller one third.

GRANT COUNTY.

PYRAMID.—The rearranging of the machinery of the mill is nearly completed, and it is expected to start up soon. The company under the new management is making every necessary improvement on the workings.

GOLDEN RULE.—The mill continues to run steadily, crushing from fifty to sixty tons per day. The mine is looking well. The ore in stopes and drifts maintains its usual grade. Four to five tons of concentrations from the mill tailings are made every day. Over sixty men are employed at the mill and mine.

HARPER.—A portion of this group of mines, in Hanover Gulch, was sold at sheriff's sale recently. The successful bids were as follows: The Superior, $175; Mountain Boy, $90; Pylmira, $70; Gray Eagle, $68; Mastodon, $84; and Milton, $64. The Mastodon prospect is a valuable claim, and cost Harper over $1000 when purchased of the original locators.

PENNSYLVANIA.

NORTHAMPTON COUNTY.

The quarries of Bangor, East Bangor, and Pen Argyl are increasing in productiveness daily. They are, says a correspondent of the New York *Sun*, hampered only by the scarcity of skilled labor. So many quarries are opening that labor is scarce. In the entire region, there is great demand for all kinds of labor. Ordinary day laborers earn from $1 to $1.35 per day, and often more, according to the exigencies of the occasion. Carpenters earn from $2.25 to $3.25. Bricklayers find work, but most new buildings are frame. Machinists are sought after daily, and make good terms, because practical men to work at the opening of new quarries and the erection of machinery are scarce. Slaters (splitters and dressers) earn from $2.50 to $4 and $4.50 per day by the piece. Quarrymen can always find remunerative employment. The growth of the industry has been very rapid.

UTAH.

WASHINGTON COUNTY—SILVER REEF.

BARRY CONSOLIDATED.—The object of this company, recently incorporated, is to operate and work the Barry group of claims, located north of the Crescent Company's property at Park City. The claims to be operated are the *Morions*, Del Norte, Rickwah, Wakell, Capell, Weilchpeck, Areata, Lagoon, Aztec, and Fountain. Salt Lake is named as the chief place of business, and the capital stock is placed at $2,500,000 in shares of $10 each, par value. A large amount of work is to be done on the property this winter.

BARBEE & WALKER.—Rumor has it that the company's mines have been closed down for an indefinite period.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Nov. 2.

There is nothing of interest in the mining market this week to report. Business continues to be very dull and uninteresting, and is confined to two or three low-priced fancy stocks. A full summary of the market is given below. The total number of shares sold aggregates 117,935, as against 136,750 last week.

The Comstock shares were very quiet at steady prices. California sold at 31c., assessment paid, and at 8c., assessment unpaid. Consolidated Virginia was moderately dealt in at irregular prices; it sold from 47@50@45c. Sierra Nevada was quiet and steady, selling from $3.75@$4. Union Consolidated was weak, under a small business, selling from $4.35 @$3.55. Mexican sold at $3.25, and Ophir at $5.25. Best & Belcher sold to the extent of 100 shares, assessment paid, at $4. Sutro Tunnel was fairly dealt in at irregular prices; it sold from 17@15@16c.

The Leadville stocks were also quiet and steady. Amie sold from 11@12c. under a small business. Chrysolite was steady, selling from $1.20@$1.15, with a business of 2400 shares. Dunkin was quiet and steady at 26c., and Breece sold at 18c. Iron Silver was moderately dealt in at steady prices; it sold from $2.95@$3. Leadville was quiet and steady at 38@40c. Little Chief sold to the extent of 1200 shares at 56@54c. Little Pittsburg was steady, selling from 58@56c. under a small business. Climax was quiet and steady at 7@6c.

There was no change of interest in the Bodie stocks. They remain very quiet at about steady prices. Bodie Consolidated sold to the extent of 300 shares at 15c. Standard was quiet and steady at $6@$6.25. Bulwer sold at 50c., and North Standard at 14c.

The Tuscarora stocks were quiet and steady. Grand Prize was strong, selling from 48@60c. with a moderate business. Belle Isle sold at 40c. Navajo was quiet and strong at $3.90. Elko Consolidated was quiet and steady, selling from 18@17c. assessment paid, and from 3@2c. assessment unpaid.

In the miscellaneous list, Alice was very quiet at $2.65. Eureka Consolidated was quite weak, under a small business, selling from $6.50@$4. Horn-Silver was moderately active at irregular prices; it sold from $6.25@$5.88@$6. The trustees of this company have decided to reduce their dividends hereafter from $300,000 to $200,000, or from seventy-five to fifty cents per share. Robinson Consolidated was quiet and irregular, selling from 42@45@43c.

Barcelona was irregular, under a small business, selling from 27@25@26c. Caledonia was moderately dealt in at weak prices; it sold from 31@30c. Decatur was very quiet at 3c. Eastern Oregon was actively dealt in and was irregular; it sold from 46@40@44c. Harlem was also very active and was steady; it sold from 92@96c. Oriental & Miller was quiet and steady at 8@7c. Rappahannock sold from 8@9c. with a fair business. Sonora Consolidated was very active at steady prices; it sold from 25@27c. Castle Creek was fairly dealt in and was steady; it sold from $1.10@$1.05.

MEETINGS.

The Clifton Hydraulic Company, No. 14 Wall street, New York City. Annual meeting of stockholders December 4th, at ten o'clock A.M.

A meeting of the stockholders of the Green Mountain Mining Company was held in this city this week, and it was announced that the company was in debt to the amount of $74,000.

The San Pedro and Cañon del Agua Company, Hartford, Conn. Annual meeting of stockholders December 3d, at one o'clock P.M.

DIVIDENDS.

The Evening Star Mining Company, of Colorado, has declared dividend No. 56, of fifty cents a share, amounting to $25,000. The total dividends paid by this company to date now reach the figure of $1,400,000.

The Horn-Silver Mining Company, of Utah, has declared a dividend (No. 11) of $200,000, being two per cent on the capital stock, payable on and after November 15th.

The Standard Consolidated Mining Company, of California, has declared its monthly dividend of twenty-five cents per share, payable November 12th at the office of the Farmers' Loan and Trust Company.

The United Verde Copper Company, of Arizona, has declared a dividend.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, No. 49 Broadway, report that the petroleum market during the past week has been exceedingly dull. The public has taken very little interest in it, and the fluctuations have been so small that there has been no encouragement to trade. The market has lost a little each day, notwithstanding the bull talk as to the future.

The monthly report was bearish for October work, and makes the following showing:

	October.	September.
Wells completed	320	300
Wells drilling	336	310
Rigs up and building	251	206
New production	4,576	4,700
Average per well	14·30	14·43

There has been a falling off in Balltown production during the past two weeks, but the total production in the oil-field is still in excess of the consumption. The pipe line returns for the month of October will show a loss of about 150,000 barrels in gross stocks, but the shipments are about 200,000 barrels less than for September. The exports were less in October than in September.

The market needs a leader, and if no one comes in to stir it up, the chances are, that prices will go still lower. If there should be a decline to say 107 or 108, we should consider oil a good purchase for a turn.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Oct. 27	$1.10¼	$1.11¼	$1.10¼	$1.10⅝	3,035,000
29	1.10⅞	1.11⅜	1.10½	1.10½	2,642,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, November 1.

The market for mining stocks continues to rule extremely dull and inactive, and there is no material change in quotations. There has been rather more Calumet & Hecla sold than usual, showing that, while some holders are willing to sell, there are others ready to take their places on a stock which is sure to pay liberal dividends for many years to come. Sales this week range from $239@$238½, mostly at the latter rates. Franklin declined on a small lot from $11¾@$11, but a sale to-day of 50 shares brought the former price. Quincy has been very quiet, with sales at $52 early in the week, but subsequently declined to $50, at which it is now offered. Pewabic steady at dull at $2½. Osceola sold at $18½, same as last week. Brunswick Antimony declined from $15 July to $10.

In silver stocks, there is absolutely next to nothing doing. A sale of 1200 shares Catalpa at 27½c. nd 100 shares Sullivan at 96⅞c. comprise all the ansactions at the Boston Stock Exchange for the week.

At the Mining Board, there is more activity n livan and a better range of prices. Salesat 97½c.@$ regular, and $1@$1.07 buyer's option. Bowman ver, dull at 11@12c. Empire, 27@28c. unkin 25@28c.

3 P.M.—At the afternoon Board, Calumet & advanced to $240. The rest of the list was unchanged.

BULLION MARKET.

NEW YORK, Friday Evening, Oct. 26.

The London market has declined in rate and one the past week, and with a weak sterling exchange market here, silver has fallen in our market, and dull at the figures of our table.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y Cents.
Oct. 27	50 15-16	110⅝	Oct. 31	50 15-16	110½
29	50 15-16	*	Nov. 1	50 15-16	110½
30	50 15-16	110⅛	2	50⅞	110⅝

* 110⅛@110⅝.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended November 2d, as compiled from various sources, amounted to $247,000, as against $153,000 reported for the previous week. The receipts from January 1st, 1883, to date are $9,563,047.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended October 27th	$255,807
Corresponding week last year	56,620
Since January 1st, 1883	12,328,959
Corresponding period last year	44,443,877

Imports.

Week ended October 27th	$599,793
Corresponding week last year	335,736
Since January 1st, 1883	14,141,847
Corresponding period last year	4,280,919

Foreign Bank Statements.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at three per cent. During the week, the bank lost £449,000 bullion, and the proportion of its reserve to liabilities was reduced from 43 15-16 to 43⅛ per cent, against 36 15-16 per cent at this date, a year ago. November 1st the bank gained £9000 bullion on balance.

METALS.

NEW YORK, Friday Evening, Nov. 2.

Copper.—The market continues quiet. Manufacturers who are doing a fair business, so far as volume is concerned, are well supplied, and enter the market only for small lots, for which they decline to pay more than 15c., while holders ask 15⅛@15¼c. Other brands are nominally 14⅛@14¾c. There is some dissatisfaction among manufacturers as to the freights on coal, ore, and metals. London is falling off again, the latest cable quotations being £61 2s. 6d for Chili Bars and £67 for Best Selected.

Tin.—The market is dull and weaker, with spot Straits quoted at 20¼@20⅜c.; and London down to £92 2s. 6d. The following statistical statement has been cabled to the Metal Exchange from London:

MOVEMENT OF TIN IN OCTOBER.

	1883.	1882.
Shipments:		
Straits to Great Britain	1,350	1,350
" " America	230	540
Total Straits	1,580	1,890

*Non-assessable. † The Deadwood has previously paid $275,000 in eleven dividends, and the Terra $75,000. ‡ This company, as the Western, up to December 10th, 1881, paid $1,475,000. Quotations of these stocks will be found in S. F., San Francisco; B., Boston; and P., Philadelphia, tables. E are British companies. ‖ Total number of shares, 500,000; 50,000 shares have never been issued, and are still held by the company. Dividend shares sold, 38,025.

Lead.—Under sales aggregating between 300 and 400 tons, the market for Common lead declined from 4·10 to 4·05c. during the week, until to-day it was announced that 500 tons of Refined lead had been sold at 4c. The fact that this transaction has been completed is questioned in some quarters, but it is indicative of the state of the market that no surprise was manifested as to its having been done in well-informed quarters. With lead at this figure, it

G. Gold. S. Silver. L. Lead. C. Copper. * Non-assessable. † Stocks quoted on S. F. San Francisco; B., Boston; P., Philadelphia. Non-Dividend shares sold, 79,910. Total shares sold, 117,935.

behoves the producers to look to the freight rates, a lowering of which can alone give them relief.

Messrs. John Wahl & Co., of St. Louis, wire us to-day as follows:

Our market has declined slowly since our last report, there being but little doing, with the demand regulated by a hand-to-mouth policy. Sales for the week sum up over 200 tons of Refined at 3·85c., and 100 tons Common at 3·80c.

Messrs. Everett & Post, of Chicago, telegraph to-day:

We note a gradual decline in our market. Business has been quiet and of a limited character, with quotations at 3·82½@3·85c. The stocks in the hands of holders are limited, and offerings are therefore on a moderate scale only. Sales aggregate 250 tons.

Spelter.—The market continues dull and lifeless, with Common and Domestic nominally at 4½c., which, however, could probably be shaded.

Antimony.—This metal is firmer, with Cookson's at 10½c. and Hallett's at 9½c.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Nov. 2.

The protracted dullness in the iron trade in this and all the other civilized countries in the world has seemed to many inexplicable. A few figures quoted by the London *Economist* will, we believe, go far toward removing much of the mystery that is supposed to cling about our present condition. The production of the three principal producing countries, Great Britain, the United States, and Germany, for the years 1868, 1873, 1877, and 1882, throw a flood of light on the subject:

PRODUCTION OF PIG-IRON.

	1868.	1873.
United Kingdom	4,970,206	6,566,451
United States	1,603,000	2,868,278
Germany	1,053,260	2,174,737
Total	7,626,466	11,609,466
	1877.	1882.
United Kingdom	6,608,664	8,493,287
United States	2,314,585	5,178,121
Germany	1,421,667	3,170,957
Total	10,344,916	16,842,365

With such figures, it is rather a matter of surprise that the reaction has not been much more violent. It will be noticed that the figures for 1868 and 1878 show a very heavy growth, which, during the period 1873-1877, received a check, and, in some instances, was followed by a decline. Then came another era of wonderful expansion, which, as we know, reached its climax last year. We, as well as others, have overshot the mark, and it is a very encouraging indication of the permanent growth in the demand for crude and manufactured iron, that the reaction has been as healthy as it has proved to be.

Mr. Edward J. Shriver, Secretary of the Metal Exchange, has the following returns to November 1st. It will be noticeable that they are in greater detail, and though the number is necessarily limited on account of the early date, it is instructive: Fourteen anthracite furnaces—four in blast, ten out of blast.

Grades.	Stocks. Oct. 1.	Stocks. Nov. 1.	Production. In Sep.	Production. In Oct.
No. 1	1,080	775	664	706
No. 2	483	412	361	405
Bessemer, with forge and lower grades	814	3,410	1,565	907
Grade not specified	3,646	.....	654	539
Total	6,723	4,597	3,244	2,557

Thirteen bituminous furnaces—four in blast, nine out of blast.

Grades.	Stocks Oct. 1.	Stocks Nov. 1.	Production In Sept.	Production In Oct.
No. 1	5,910	5,000	250	300
No. 2	350	.....	200	100
Bessemer, with forge and lower grades	4,454	3,800	644	700
Grade not given	500	500	2,000	1,900
Total	11,214	9,300	3,094	3,000

Fourteen charcoal furnaces—ten in blast, four out of blast.

	Stocks. Oct. 1.	Stocks. Nov. 1.	Production. In Sept.	Production. In Oct.
All grades	8,242	8,129	2,535	2,650

Forty-one furnaces, all kinds—eighteen in blast, twenty-three out of blast.

All grades.	Stocks. Oct. 1.	Stocks. Nov. 1.	Production. In Sept.	Production. In Oct.
Anthracite	6,723	4,597	3,244	2,557
Bituminous	11,214	9,300	3,094	3,000
Charcoal	8,242	8,129	2,535	2,650
Grand total	26,174	22,026	8,873	8,207

American Pig.—The market is fair, with a moderate business doing compared with the absolute stagnation of the past month. For this season of the year, the transactions are decidedly limited, and October has passed by with no better features than November, and there seems no immediate prospect of a revival in the demand. Foundry iron remains $20 $22 for No. 1 and $19@$20 for No. 2, with Gray Forge at $17.50@$18.50 at tide-water. Bessemer pig is dull, and with the lower prices for rails, will not find buyers except at very close figures. We quote $20@$20.25. Spiegeleisen is quiet at $30 for 20 per cent.

At the Exchange, the following sales were recorded: Friday, 100 tons No. 1, $19.50.

Scotch Pig.—There is very little to report, the situation remaining unchanged, with a light business and moderate supplies.

We quote ex ship and to arrive: Coltness, $23; Langloan, $23@$23.25; Summerlee, $22.50@$23; Eglinton, $20.50@$21; Glengarnock, $21.75@$22; Dalmellington, $20.75@$21.

At the Exchange, the following cable quotations were received to-day: Coltness, 56s. 3d.; Langloan, 55s. 6d. · Summerlee, 53s. 6d.; Gartsherrie, 54s. 6d.; Glengarnock, at Ardrossan, 53s.; and Eglinton, at Ardrossan, 47s. Warrants at the Exchange to-day were 44s. 10d.

Rails.—To-day, the Lackawanna Company announces the sale of 30,000 tons of steel rails at mill at $35 for winter delivery, the result of the feeling which we foreshadowed in earlier reports. This means simply that the best located mills in the country are determined to run full by securing the business. At such figures, some of the mills must close down to wait for better times, and in confirmation of this we are informed that the Troy works have temporarily closed their Bessemer works, which will run only at intervals to supply the merchant steel department, which does not call for its full capacity.

Other agents claim to have sold this week several lots at as high as $37 at mill, but it is not probable that buyers, under the circumstances, will henceforth place orders at more than $35@$35.50 at mill, according to time of delivery, section, etc.

Old Rails.—The market has shown more animation under lower figures. We quote $21@$22 for Tees.

Scrap.—We quote $23 ex ship.

Philadelphia. November 1.

Pig-Iron.—Between 12,000 and 15,000 tons of low-priced irons have been sold during the past few days, and there are inquiries in hand at present writing which will probably result in the placing of several additional large lots, although prompt delivery will not be insisted upon. There is more speculative feeling in the market this week than for many months. The reason of the increased activity is not owing to increase in consumption so much as to the belief prevalent in well-informed iron circles that the present exceedingly low prices are the lowest probable, and that now is the proper time to buy. This feeling has brought out several large consumers, and will result in the covering of requirements for a few weeks a least. An upward tendency would develop a further activity in the better grades. Thus far, business has been confined to low-priced irons chiefly. There are rumors of a further drop of 50 cents on special and standard makes, but inquiries show that there were only some shadings of about 25 cents on large lots. A few special brands are still held at outside prices, but most of the business done in specials is at the rates prevailing three or four weeks ago. Ordinary quotations are $20.50@$21.50 for No. 1 Foundry, and $19@$20 for No. 2. There is no difficulty in obtaining supplies of desirable iron at $19@$20.50, and sales have been made at lower figures. The activity referred to has been especially in mill irons, and prices range from $17@$19, tide-water, though very little is selling at the latter figure. A large amount of white and mottled iron has been sold at inside quotations, and some speculative inquiry prevails, and Western iron is offered for delivery in Eastern Pennsylvania.

Foreign Irons.—Bessemer is quoted at $20@$21. Sales can be made at $20, and negotiations are in hand at that price, but for moderate-sized lots. The attempt to move large lots has failed, even with the offering of heavy concessions. American Bessemer is finding more acceptance, and orders for foreign are hard to place. Brokers of Scotch irons are in receipt of a number of orders for small lots for delivery in Eastern Pennsylvania. Spiegeleisen is $30@$31. A few small lots have been asked for, but business is moderate.

Blooms.—A weakening of 50 cents in Blooms has brought out orders for a few hundred tons for delivery next month, especially of anthracite.

Steel Rails.—Sales have been made at $36.50. Small lots, $37@$38.

Merchant Bar.—The same unfavorable condition continues, and nothing new can be stated. There is some speculative inquiry, but, so far this week, offers have not been excepted, and neither holders nor sellers seem anxious to do business in the present condition of the market. Manufacturers argue that a change for the better is not far off, and that the present policy of reducing output will bring about an improving tendency in a very short time. As long as iron can not be sold at more than cost, the restriction will continue. Business has been done in 50 to 100-ton lots; card rate, 2·20c.; but iron can not be sold above 2·15c., and considerable quantities have been sold at 2c., and even below this figure in country mills. The car-works are calling for retail lots of iron, and pay from 1·75c.@1·90c. Business is promptly accepted at the best terms that can be had.

Plate and Tank Iron.—No large orders have been placed, but the average run of business is fair for delivery during the next two months. Buyers do not anticipate any further decline. Quotations, 2·35@2·40c. for Boat Plate; 2·40@2·50c. for Tank. Quotations for shell and flange are fluctuating, and inside prices can not be given for some large lots which have been ordered. Small lots of Shell, 3@3·25c. Flange, 4@4·25c.

Structural Iron.—Some brokers have had scattering inquiries for large and small lots, but no large business has been done, although there are evidences that the requirements known to exist will bring buyers into market during the present month for large lots. A great deal of bridge iron will be wanted this fall and winter. While other departments of the iron trade are suffering, the structural mills seem to be receiving a fair volume of business.

Nails.—There is less activity in nails this week, because of the fact that jobbers have quit ordering. Quotations, $2·80@$2·90. Some interest is felt as to the probable action of the Western nail-makers, who will meet in ten days to determine the question of restriction.

Old Rails.—Nominal quotations are $23.50 and $25.50 for Foreign, and $24 asked for American.

Pittsburg. November 1.

Pig-iron remains dull and unchanged. Demand is very light, and orders are placed for pressing requirements only. No. 1 Foundry sells at $20@$21; No. 2 at $18@$20, with better inquiry, but no large moving. Gray Forge, $17.50@$18.50, four months. There is no prospect of any improvement for some time to come, but no further decline is apprehended at present. Steel rails are quoted at $38@$38.50 for small lots, November and December delivery, but $37 has been taken for several good-sized lots for delivery during the early part of next year. The long talked of suspension of nail production has again been postponed, as the stocks are found to be quite light. Carload lots sell at $2.70, and smaller lots $2.80@$2.85. The usual amount of business is done. There is an increased activity in Merchant Bar, but prices are as usual, 1·80@1·90c., and no requirements are anticipated. Muck Bars are in moderate demand, and some sales have been closed at $33 cash, but $33.50@$34 time. Bessemer is quoted at $21@$21.50. There is no improvement in old rails or scrap. The whole trade is dull, and there is no immediate prospect of any improvement either in demand or prices.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Nov. 2.

Anthracite.

Our local market is very dull, and shows a decidedly weakening tendency, under the pressure of threatened accumulations. With the exception of some kinds of stove coal, the shading is increasing, and good buyers have little trouble in driving good bargains. The old-time threats, so often repeated, have no effect nowadays on the buyers, who have learned by experience during the past few years how much there is in them. There seems little prospect that any action will be taken during this month to carry out the policy of restriction, though it would be idle to deny that insisting upon full-time work must strain what is so often called the harmonious relations of the companies.

Much is made of the demand for the coal in the West, and there is no doubt that many of the dealers there are behind in their orders. Anthracite has been pushed further Westward this year than ever before, and though the quantity has been heavy, the nearer-by points like Chicago are a little behind. How much of the urgency of the Western dealers is due to the fact that they are anxious to get coal contracted for months ago at the prices and freight rates then ruling is another question. In any case, the lack of cars puts a limit to this source of relief to this market, and, in spite of the cries from the West, coal accumulates here. The Lehigh & Wilkes-Barre Company, we may here note, has also begun shipments to the West this week.

Bituminous.

The trade continues dull, the only feature being a stiffening in freights.

Horsford's Acid Phosphate.

For Lemons or Lime Juice,

is a superior substitute, and its use is positively beneficial to health.

HORN-SILVER MINING COMPANY, 44 WALL STREET, New York.

DIVIDEND NO. 11.

A dividend of $200,000, being two per cent on the capital stock, will be payable to stockholders of record on and after November 15th, at the office of the company. Transfer-books will close Wednesday, November 7th, and reopen November 16th.

W. S. HOYT, Secretary.

THE reduction of the price of steel rails to $35 at mill, which we announced in our last week's issue, has created a good deal of comment. To our minds, the most serious feature in connection with it is, that it throws an unfavorable light on the future rather than the present condition of the iron trade. Rails, more than any other specialty in the iron and steel trades, are ordered generally many months ahead, and the rail business, therefore, may be said to reflect, more accurately than any other, what will be the requirements of the most important consumer, the railroads. People are apt to point with satisfaction to the fact that, in the first ten months of the year, the mileage of our railroads increased 5000 miles. Unfortunately, the great bulk of all the iron-work needed for such new roads has probably long left the mills and foundries. The business they are doing at present confirms the conclusions one can not help drawing from the condition of affairs in the financial centers of the country, that the iron and steel trades can not look for much relief to the railroads and the many allied industries dependent upon them.

LEAD producers are beginning to show alarm at the course of values, and of late there have been a good many conflicting statements as to stocks, production, consumption, etc. It has been repeatedly stated that, through the maliciously inspired reports, notably of Eastern newspapers, a very false impression has been conveyed to buyers, and that much injury to legitimate trade has thus been wrought. So far as we can judge by an impartial survey of the situation, some of the "bear" articles referred to have been exaggerated. On the other hand, it is ridiculous on the part of producers—who profess with angry vehemence that the trade is in an ideal position, and quietly sell their metal right and left—to expect their statements to be accepted as gospel. The lead trade has, during the past few months, learned how dangerous is a little knowledge in the hands of outsiders. The times have passed by when the state of a large and important industry can be wrapt in mystery, and the lead producers and refiners would do well to accept the situation and guard against future troubles by a simple measure. They should form an association, something like the American Iron and Steel Association, which in critical times gives to the public absolutely reliable data as to the statistical position, watches the course of developments here and abroad, and at all times defends and protects the interests of the industry it represents. Such an association ought not to attempt to regulate prices or production. The sorry attempts made years ago by the association at St. Louis proved how little chance there is of success in that direction.

MODEL MINERAL STATISTICS.

In a recent issue, we referred to the first attempt made by a department of the government, the United States Geological Survey, to collect annually statistics of the production of the mining and metallurgical industry of the country. The work, considering the circumstances under which it was done, was very well performed indeed, and, from the expressions of approval coming from different quarters, has met with much appreciation. Yet few in this country probably have any idea of the completeness to which such statistical work has been brought elsewhere. Under the circumstances, we have believed it appropriate to quote at length from the report of the Prussian Department of Mines, a simple abstract of which we have generally printed in years past. We simply tabulate the footings, to show how far the inquiry of the government statisticians extends. Beginning with coal, lignite, etc., we have the following for 1882 :

	Bituminous coal.	Lignite.
Non-producing mines :		
Mines in course of development.....	14	6
On account of alterations.....	3	....
Hoisting waste rock only.....	....	1
Stopped for other reasons.....	....	4
Mines producing :		
Mineral mentioned as main product.....	382	419
Mineral mentioned as by-product.....	1	1
Total production, tons.....	47,097,376	10,798,091
" " value, marks....	232,724,491	29,570,722
Quantity used for own purposes, or wasted on dumps.....	2,960,988	907,213
Value thereof, marks	32,927,465	2,633,011
Marketable product, tons.....	44,136,388	9,890,878
" " value, marks.....	218,797,026	26,937,711
Value per ton, marks.....	4·96	2·72
Number of persons employed, total.....	171,610	20,108
Under ground.....	135,970	10,508
Above ground, men.....	32,416	9,258
" " women.....	3,224	342

In a similar manner, full details are given concerning graphite, which was mined to the extent of 38 tons ; asphaltum, of which 12,996 tons was produced ; petroleum, the wells yielding 5989 tons ; rock-salt, of which two mines turned out 210,129 tons ; kainite, which was produced to the extent of 141,272 tons ; and other alkali salts, figuring up to 553,029 tons. The iron and metalliferous mines had a record, from which we cull the following data :

	Mines producing.	Net output dressed ore.	All men employed.	Men below ground.
Iron ore.....	679	3,987,273	30,475	20,736
Zinc ore.....	115	693,369	12,750	6,976
Lead ore.....	121	155,803	18,562	10,130
Copper ore.....	84	558,850	12,787	10,966
Silver and gold ore.....	2	114	219	170
Cobalt ore.....	1	66	69	62
Nickel ore.....	7	14	..	..
Antimony ore.....	1	42	20	12
Arsenic ore.....	2	451	64	41
Manganese ore.....	23	4,130	238	70
Pyrites.....	25	157,960	827	454

The work of the salines is accounted for in a like detailed manner ; but what interest us particularly are the statistics of the production of the metallurgical works of the kingdom. We can, in our own country, boast of the elaborate and accurate figures published by the American Iron and Steel Association, and Mr. SWANK brings out some valuable features which we miss with our German friends. The following is a summary of the pig-iron statistics of the latter, which, we may add, the

Digitized by Google

labors of the German Iron Manufacturers' Association are now supplementing in some points:

	Charcoal.	Coal or coke.	Mixed fuel.
Number of works	23	77	2
Men employed	1,488	15,730	29
Women employed	4	887	5
Output as main product	31,623	2,205,571	2,837
Output as by-product	231	226,905	380
Total product	31,854	2,432,476	3,217
Total value, marks	3,653,309	145,933,838	215,404
Value per ton, marks	114·69	59·99	66·94
Materials used:			
Domestic ore, tons	76,011	4,748,438	7,727
Imported ore, tons	822	712,645	.....
Of total ore received in roasted form	3,989	754,192	1,100
Domestic scrap	362	17,089	.....
Imported scrap	82	1,600	.....
Limestone	5,002	1,671,391	1,561
Domestic cinder	1,065	530,796	135
Imported cinder	.....	7,331	.....
Blue billy	.....	7,239	.....
Miscellaneous	108	528	.....

Figures such as these present a better estimate of the average yield of ore in the furnace than that which was attempted some time since in England, without taking into account the scrap, cinder, etc., the use of which is now largely increasing everywhere. It is to be regretted that no effort is made to add the quantity of fuel consumed.

The statistics of the spelter industry are particularly interesting, because Germany is the most dreaded of our competitors. We therefore reproduce the figures by districts:

	Silesia.	Westphalia.	Rhine Provinces.	Total.
Number of works	24	2	5	31
Men employed	4,031	1,348	1,550	6,929
Women "	1,243	6	11	1,260
Total product, tons	69,846	13,346	25,089	113,271
Domestic ore used, tons	502,166	36,272	56,760	595,197
Imported ores used, "	2,202	2,462	17,971	22,635
Including roasted ores	45,368	96	17,066	62,521
Other materials	9,863	57	165	10,085
Total ores and materials	514,231	38,791	74,895	627,918

These figures clearly show the distribution of the enormous spelter industry of Germany. They prove how largely the Rhine Provinces are dependent upon foreign supplies. The average yield of the ores and materials worked is about 20 per cent, their percentage of metal of course being considerably higher.

We can not now enter into details as to the production of lead, which footed up to 86,811 tons of pig-lead and 2739 tons of litharge. Nor can we do more than note in passing that the copper produced has reached 14,886 tons, of which the Mansfeld District is credited with 11,724 tons. One works in the Rhine Provinces made 2019 tons of copper from 63,963 tons of roasted imported pyrites, presumably Rio Tinto stuff, and 9940 tons of domestic material, using 2140 tons of iron, 6087 tons of salt, and 1713 tons of hydrochloric acid. The product of silver of Prussia was 161,519·82 kilograms of silver and 81·74 kilograms of gold, while the yield of nickel was 121 tons. Prussian acid-works turned out 211,824 tons of sulphuric acid, using 124,241 tons of domestic and 40,144 tons of imported pyrites, and 1234 tons of saltpeter.

Special returns are made in reference to the iron industry, which we summarize as follows; leaving out the details of the furnaces running on charcoal and mixed fuel, as of minor importance:

	Coal or coke.	Total.
Number of furnaces	206	237
Furnaces in blast during year	170	197
Total time of running, weeks	8,055	9,080
Product:		
Foundry pig	107,403	120,252
For steel manufacture, including spiegel	998,585	1,000,570
Forge pig	1,303,678	1,307,485
Direct castings:		
Machinery	746	918
Pottery	403	6,982
Pipes	6,500	6,504
Other castings	10,164	14,885

It will be noted how small a proportion of the pig produced is used for castings made directly from the furnace, and how small is comparatively the quantity of foundry pig made in Germany, in spite of the fact that, as the following figures, unique in their kind, show, the foundry business is one of magnitude:

THE PRODUCTION OF PRUSSIAN FOUNDRIES.

Number of foundries	137
Foundries connected with iron-works	85
Foundries connected with other works	436
Total	658
Hands employed	25,293
Plant:	
Cupolas, total number	1,256
" working	777
Reverberatory furnaces, total number	112
" working	89
Other furnaces, total number	280
" working	234
Material:	
Domestic pig, tons	181,617
Imported " "	158,899
Domestic scrap "	141,222
Imported " "	6,493
Total material	488,231
Product:	
Machinery castings	195,844
Pottery	30,290
Pipes	56,193
Chilled castings	11,963
Malleable castings	5,370
Miscellaneous castings	125,320
Total castings	424,979

The details in regard to the manufacture of wrought-iron are similarly elaborate:

Total number of works	263
Hands employed	46,152
Plant:	
Finery fires, total number	143
Finery fires working	110
Puddling-furnaces, total number	1,985
Puddling-furnaces, working	1,614
Rotary puddling-furnaces, total number	2
Rotary puddling-furnaces, working	1
Welding-furnaces, total number	1,064
Welding-furnaces working	809
Reheating furnaces, total number	543
Reheating furnaces working	477
Other furnaces, total number	219
Other furnaces working	192
Material used:	
Domestic forge pig, tons	1,528,053
Imported forge pig, tons	13,905
Loups and muck bar purchased	101,337
Scrap and old material purchased	158,823
Product:	
In finery fires, tons	18,599
In puddling-furnaces, tons	1,389,217
In other furnaces, tons	77,704
Marketed:	Tons.
Loups and muck bars	61,907
Rails	4,228
Track material	7,136
Railroad axles	219
Railroad wheels	6,505
Tires	2,857
Iron railroad ties	26,945
Fastenings therefor	2,227
Merchant bar	326,643
Fine bar	118,802
Coarse shapes	104,425
Shapes for bridges, ships, etc	105,429
Forgings	9,845
Parts of machinery	4,735
Boiler-plate	131,805
Sheet-iron, above 0·04-inch gauge	62,095
Sheet-iron, below 0·04-inch gauge	48,161
Tin plate	10,109
Wire	239,915
Tubes	6,400
Other kinds	30,019

The most noticeable figures are the insignificant quantity of rails, the large amount of iron sleepers or ties, and the heavy quantity of wire, in which the German iron industry leads the world.

The details of the steel industry are of particular interest:

Number of works	64
Hands employed	27,288
Plant:	
Bessemer converter, total number	61
" " working	48
Open-hearth furnaces, total number	59
" " " working	40
Crucible furnaces, for making steel, total number	6
" " " " " working	4
" " for melting steel, total number	285
" " " " " working	143
Cupolas, total number	120
" working	90
Reverberatories, total number	22
" working	4
Reheating furnaces, total number	581
" " " working	362
Other auxiliary furnaces, total number	49
" " " working	38
Material used:	
Domestic pig, tons	795,038
Imported pig, tons	120,354
Spiegeleisen, tons	130,139
Ferro-manganese, tons	5,165
Wrought-iron, tons	1,199
Steel purchased, tons	110,097
Old iron and scrap, tons	186,350
Steel purchased for crucible steel, tons	8,450
Iron purchased for crucible steel, tons	4,026
Product:	
Bessemer steel, tons	911,316
Open-hearth steel, tons	154,214
Other kinds, tons	5,096
Crucible steel, tons	36,215
Marketed as:	
Billets, tons	67,887
Crucible steel, tons	10,293
Rails, tons	479,093
Track material, tons	26,510
Axles, tons	17,846
Wheels, tons	28,871
Tires, tons	37,818
Sleepers, tons	47,116
Material for sleepers, tons	27
Ordinary merchant bar, tons	9,148
Fine steel, tons	13,673
Shapes for bridges, etc., tons	1,819
Machinery, tons	9,532
Guns and projectiles	12,176
Forgings	633
Ingots and blooms	71,388
Plates	1,350
Boiler-plate	3,241
Sheet-steel	4,341
Wire	123,532
Castings	151
Other articles	68,531

In all cases we have given merely the totals. The original report contains the same details for every one of the sixteen government districts, and these furnish a very close idea of the geographical distribution of the various industries without revealing private business. We do not wish to imply that it would be possible, even if it were desirable, to go into such detail in this country. We believe that it would in all cases be better to sacrifice absolute accuracy to prompt publication. A well-conducted census every ten years would be ample for all practical purposes, so far as the mass of less important data is concerned. It is humiliating, however, to be forced to confess that, so far as a large number of important industries are concerned, we have not, until this year, even made the attempt to collect them officially. It is to be hoped that in the future, figures for at least their total product will be gathered annually.

Digitized by Google

THE NEW YORK MEETING OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

On Friday morning, special cars took the members to

THE WORKS OF THE YALE & TOWNE MANUFACTURING COMPANY, AT STAMFORD, CONN.

The party first visited the iron and brass foundries, in a well-lighted and ventilated building, containing a five-ton Weston jib crane, the construction of which was described by Mr. Towne. Special attention was directed to the furnaces with independent draught, used for brass melting, to the brass molding from ornamental and very light patterns, and to the use of band-saws for cutting off the gates of the castings. After visiting the cleaning, pickling, and tumbling rooms, the party went to the pattern-shops, for both wooden and metal patterns, on the second floor of the foundry extension, and then entered what is known as the "Post-Office" building, from the fact that it is devoted to the manufacture of post-office equipments, chiefly wood-work. The wood-working machines are on the lower floor, and the upper floor is used for erecting. In busy times, this floor frequently contains six or eight post-offices, in different stages of completion. The metallic fronts for lock-boxes are made in the lock department and fitted to the wood-work in the "Post-Office" building. Special attention has been given to guarding against fire by the application of the overhead steam heating system in the east end of this building, and the use of overhead automatic sprinklers. Crossing the yard, the pulley-block shop was next visited. This is devoted to the manufacture of the Weston differential pulley-blocks, and the chief point of attraction is the chain-shop, in which are made all the chains used in the Weston pulley-blocks, cranes, and hoists. The smaller sizes are all made from Norway rods, and the larger sizes from American iron of high ductility. The gauges used by the chain-makers are slightly below standard pitch. After being forged, the chains are brightened by rattling, and then stretched in a special machine up to the final pitch or gauge. The strain thus applied is within the elastic limit, but has the effect of bringing the links to a permanent bearing with each other, and of giving such set to them that, when used within the intended limit of load, they will not alter their length. In this way, a chain of uniform and permanent pitch is obtained, and one having the high qualities necessary for crane work. The members were next conducted to the old "crane-shop," now fitting up for testing-machine and scale work. They were here shown a six-ton Weston hand traveling crane, which was operated and its construction explained, after which lunch was served.

After lunch, the visitors were conducted to the engine-room and boiler-house, containing a 20 by 42-inch Harris-Corliss engine, running 72 revolutions and developing about 125 horse-power; also the pit containing the hot-well, into which the condensed water from the entire heating system of the works is returned, and containing also Worthington duplex pump, Berryman heater, etc.; also a battery of six tubular boilers, built by Beach & Son, of Hartford, with patent water-fronts (dispensing with all brick setting about the fire-door), and Jarvis furnace setting, by means of which slack coal and other refuse is used as fuel, the present mixture consisting of one part of bituminous slack to four parts of anthracite pea and dust.

The party next entered the crane-shop by the gallery containing the coat and wash-rooms, from which an excellent view of the shop was obtained. The shop is 100 feet wide and 300 feet long, is divided into three aisles or bays, the center one having a clear span of 50 feet, and being used for heavy work and erecting and shipping purposes, the side aisles containing benches and light machine tools. Two Weston power traveling cranes, one of 20 tons and the other of 30 tons capacity, are in operation here, and their mechanism was explained by Mr. Towne. An exhibit of hand-hoisting appliances was also inspected. A short visit to the new —not quite completed—hammer-shop followed, and then the party were conducted successively through the small lock department, devoted to the manufacture of rim and mortise door-locks, large use being made of profiling machines; the tool-room, where special tools and appliances required in the lock department are made; and the "wheel-room." In the latter, some twenty-four men are employed in emery-grinding, and it is to be noted that the atmosphere of the room is perhaps more free from dust than that of any other room in the works. The removal of the injurious brass and emery dust is accomplished by large exhaust-fans in the basement, the peculiar form of the hoods covering the wheels, and of the orifice leading from these to the exhaust-tube, being important features.

Ascending another stairs, a brief visit was made to the plating department, the first room of which contains the acid and soda-tanks, etc., the second the buffing-lathes for polishing by means of rag wheels, and the third the plating appliances, including the depositing-tanks, dynamo-machines, etc. Leaving the plating-room, the party entered the room in which the 75-ton Emery hydraulic testing-machine is temporarily erected, and where a short series of tests of materials was made in the presence of the members. The testing-machine is similar in general principles to the 400-ton government machine at the Watertown Arsenal, but is of the upright type. It has a straining capacity of 151,000 pounds, applicable to tests of tension, compression, and transverse loads. It will receive specimens for tension up to 74 inches in length, and for compression up to 88 inches in length, with ample allowance for elongation. The supports for transverse strains can be separated 84 inches, and specimens of any length can be inserted. The construction and action of the machine were explained verbally during the process of making the tests.

THE EVENING SESSION.

After a brief discussion of the plan proposed to elect the officers of the society, Mr. C. J. H. Woodbury presented a lengthy paper entitled

EXPERIMENTS UPON NON-CONDUCTING COVERINGS FOR STEAM-PIPES,

giving the details of tests made by Professor Ordway, for the Boston Manufacturers' Mutual Fire Insurance Company. We may have occasion to refer to this paper at some future period. Suffice it to say, that its conclusions were attacked on the ground that these were not carried out on a larger scale, and by methods more closely approximating actual practice. Mr. Emery held that even their value as giving comparative data was open to doubt, and he gave some interesting figures to show how small the condensation was in four miles of the pipe, two thirds of it over 15 inches in diameter, of the New York Steam Heating Company in this city, the underground pipes of which are covered with mineral wool.

Mr. E. D. Leavitt, Jr., consulting mechanical engineer of the Calumet & Hecla Mining Company of Lake Superior, cited the fact that at those mines 8-inch pipes more than five hundred feet long were used to carry steam from the boilers to the engine. Formerly, when laid in a simple launder, the condensation in them amounted to several hundred gallons per hour. He covered the pipe with a mixture of plaster of Paris and sawdust, costing approximately 12½ cents per square foot. Before the covering got dry, the condensation increased; but when once thoroughly dry, it decreased until it was less than one per cent of what it had been before. This kind of covering was first introduced by Chief-Engineer Isherwood at an iron-works in Baltimore, where, with 1 inch of hair felt over it, there was a decrease of 95 per cent of the condensation. Mr. Leavitt now applies it for boilers generally, putting on a 2½-inch layer of a mixture of one part, by volume, of plaster of Paris, and two parts of saw-dust, made into a mortar, and putting above that a 1½-inch layer of felting, and in spite of the fact that at the Calumet & Hecla the temperature runs below zero only a few feet from the boilers, there is no noticeable increase in the quantity of fuel consumed, in summer or in winter.

By special request, Professor Thurston gave a brief abstract of his paper on the Theory of the Turbine, lack of time preventing a thorough consideration. Professor Hutton, the secretary, then read the following papers by title, Motive Curves for the Slide-Valve, by A. W. Robinson, and Compression as a Means of Governing Engines, by Harris Tabor. Before adjournment, the customary resolutions of thanks were offered.

On Saturday, the members, by invitation of the New York, West Shore & Buffalo Railroad, took a trip over the road to Kingston, N. Y., inspecting the exceptionally extensive terminal facilities at Weehawken, and the generally high character of this new road, which has had to contend with so many engineering problems in its construction.

A NEW GLOSSARY OF MINING TERMS.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: At first thought, it would seem that this field had been so often gone over and so fully ransacked that little room was left for a fresh compilation. But a glance at the new glossary published in the Report of the Director of the Mint on the Production of Gold and Silver in the United States for 1882 (pp. 753–763) will show that such a view is erroneous. This contains much that will be novel to mining men, and many of the definitions are so strikingly original that it is worth while to append some of the best:

"ADIT-LEVEL.—A tunnel driven for effecting the general drainage of a mine, being designed to receive and carry off the water, both above and below its level."

"ALLUVIAL [*sic*].—Deposits of mud, sand, gravel, etc., made by running streams, more especially the deposit left along their banks during high water."

"AMALGAMATION.—The process by which metals are separated from their ores by mixing them with mercury."

"APRON.—A canvas-covered frame set at such an angle in the miner's rocker that the gravel and water in pouring over it are carried to the head of the machine." No reference to the aprons of gold mills.

"ANTICLINAL.—The line of a crest above or underground, on the two sides of which the strata dip in opposite directions."

"ARRASTRA.—A Mexican contrivance for crushing and amalgamating ores by means of a heavy stone dragged around upon a circular bed." This single-drag apparatus is something rare.

"BAR.—A band of hard stone or rock crossing a lode."

"BASE METALS.—The metals not classed *as valuable* or precious." Not copper? Nor lead?

"CAGE.—A *box* or platform used for hoisting in a vertical shaft."

"CAP.—A vein is in a 'cap' when it is much contracted."

"CAP-ROCK.—The uncertain upper rock that covers the older bed-rock."

"CHILIAN MILL.—An improved arrastra, in which a heavy stone wheel is rolled around the circular bed." How about the iron ones?

"CREVICE.—A narrow opening resulting from a split or fissure." Or from a fault?

"DAMP—BAD AIR.—Choke-damp; fire-damp."

"DEPOSIT.—Mineral deposit, or ore deposit, is used to designate the natural occurrence of mineral or ore sufficiently rich to warrant its being worked."

"EPIDOTE.—A mixture of alumina and silica forming a variety of granite; often of beautiful color and shape."

"ERUPTIVE.—The name given to rocks that have burst through other rocks in a molten state, *or that have been thrust up bodily*."

"EXPLOSIVES.—The explosives used in mining are gunpowder, *nitro-glycerine*, dynamite, etc."

"FEEDER.—A small vein joining a large one at nearly right angles."

"FIRE-DAMP.—Light carbonated hydrogen gas. . . . ."

"FISSURE-VEIN.—A fissure or crack in the earth's crust filled with mineral."

"FLOURING.—The covering, in the course of using, of the globules of mercury used in gold" [and silver?] "extraction with a thin film of the sulphide of some other metal by which the gold" [or silver?] "is lost; sometimes called sickening." The compiler evidently does not believe in mechanical flouring.

"FLUME.—An artificial water-course."

"FLUX.—Any substance that is favorable to fusion, oxidation, or reduction by fire." Wax?

"FREE-MILLING ORE.—Ores in which the precious metals are free from combination with other substances, and can be reduced by crushing and amalgamation without roasting or chemical treatment." Horn-silver, argentite, etc., should therefore be roasted or subjected to "chemical treatment."

"GALENA.—Sulphide of lead; the ordinary lead of commerce."

"GRIZZLY.—A grating to catch and throw out large stones from sluices." Not used in mills, apparently.

Digitized by Google

"GROUND-SLUICE.—A long box with suitable chinks for retaining the gold, used by gravel miners for washing away large quantities of auriferous *débris*."

"HEADING.—The under side of a lode or vein above a drift."

"HORN-SILVER.— . . . So called because it has a horn-like surface."

"HORSE.—The dead or barren rock or ground by which a vein is sometimes split horizontally into two."

"HUNGRY.—Hard, barren vein matter, *like quartz*."

"IN PLACE.—An ore-deposit occupying the place in which it was originally found."

"LEVEL.—A horizontal passage or drift into or in a mine."

"MATTE.—The product of the first incomplete reduction of an ore."

"MILL.—Works for reducing ores by other means than smelting."

"MULLER.—The iron shoes dragged around in an amalgamating pan to mix and further pulverize the pulp."

"NODULAR.—Having a blistered appearance . . . "

"ORE.—The parts of a vein containing a useful or salable metal."

"PAY-STREAK.—In placer mining, a rich strip of gold-bearing gravel."

"RIFFLE.—A *groove* in the bottom of a sluice to hold the quicksilver and catch the free gold."

"ROASTING.—Ores submitted to the action of flame until sulphurous and arsenious fumes cease to be given off."

"ROCKER.—A long sluice-like box for washing away gravel from gold by cradle-like rocking."

"ROCKING.—The process of separating ores by washing on an incline plane."

"SCREEN.—A sieve of wire-cloth or perforated sheet-iron, used to sort ore according to size."

"SHAFT.—A pit, or well-like excavation, sunk from the surface."

"SLAG.—The melted gangue from furnace smelting and assaying of ores."

"STOPING.—Excavating ore from a vein by driving horizontally upon it a series of workings, one immediately over or under the other."

"SUMP.—A pit sunk from the bottom of a mine, either to probe a ledge or collect water."

"TAILINGS.—. . . or what passes away from reduction-works after any systematic treatment."

"TUNNEL.—A level driven at right angles to the vein which it is desired to reach."

"UNDERLIE.—The departure of a vein or stratum from the vertical."

"VEINOUS.—Rock or matter from the vein, and not 'bed-rock' or 'country.'"

"WATER-COURSE.—An artificial channel for passage of water."

The compiler has exercised a critical selection of terms, introducing such obscure names as cañon and gulch, yield and output, alloy, anneal, assay, caved, crushing, *ingot*, etc., and carefully omitting all lingo common to the tender-foot; as, for example, skip, skeet, whip, compressor, blower, fan, reel, drum, sheaves, gallows-frame, baby-hoist, cable, Cornish pump, water-jacket, speiss, pan, settler, agitator, table, sluice, slime, giant powder, exploder or cap, fuse, slickens, names of rocks and ores, etc. This feature adds to the convenience of reference. We note with sorrow, however, that the printer has taken liberties with some of the definitions. Thus batea appears as "bateau," a fault is described as a "discoloration," hose becomes "horse," etc. It is too bad that typographical errors should be allowed to mar the beauty of this unique work. ‡

AMONG THE IRON WORKERS.—JOHNSTOWN.

EDITOR ENGINEERING AND MINING JOURNAL:

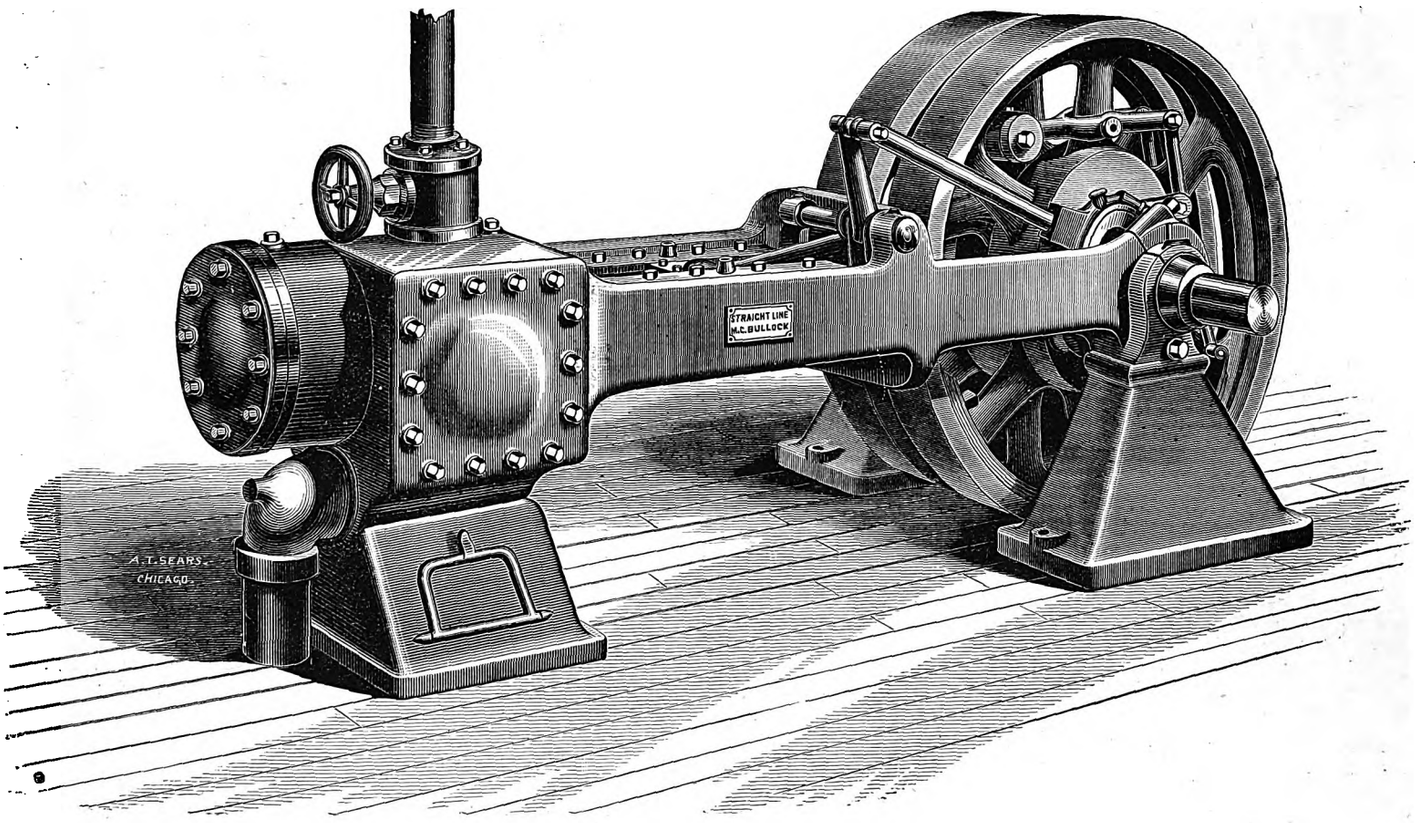
SIR: At Altoona, I asked a Johnstownian about the hotels I would find at his native place, and his description I afterward found to be too true. "There are but two hotels of any pretensions," said he, "and whichever one you go to, you will wish that you had taken the other." Thus encouraged, I sought out the Merchants' Hotel, when I reached Johnstown on Saturday evening. At the station, I asked for directions to take me to mine inn, and with rather a vague idea, I started out to follow them. Their want of definiteness, however, soon became too apparent, and I had to apply to a young traveler for further information. After getting the desired directions, I asked the young fellow if this were not the best hotel, and had my purpose well-nigh upset by his answer, "No, indeed, the other is much better;" and not content with directing me thither, he started out to accompany me. It struck me that such unusual attentions might not be disinterested, so I thanked my would-be guide, and said that I would first get my mail and search for a hotel afterward. He proved the kindness of his purpose, however, by taking me to the office, and, having given me very full directions, he bowed himself off. Though the Merchants' fulfilled its description entirely, yet I was not sorry that I had carried out my original intention; for at the supper-table, I was fortunate in finding an old college friend; and the circumstances of our meeting added greatly to the pleasure of my visit.

The life of Johnstown, and indeed almost the *raison d'être* of its existence, is the Cambria Iron Company. The city itself is rather complex in its organization. It includes several neighboring boroughs, and in all boasts of something like eight thousand inhabitants. Its location is rather peculiar. In the very heart of the mountains, the town-site is nearly level. On all sides, the town is surrounded by steep hill-sides; and in this lies its peculiarity that, when one reaches the top of the hills, instead of finding corresponding valleys on the other side, he finds simply an elevated table-land, on which many productive farms are located. The city seems to be situated in a marked depression of an otherwise level plateau. The streets of the place have no gradual changing to steep grades, but are beautifully level until they seem to terminate against the steep hills. The town has shared the success of its great company. With the growth and prosperity of their furnaces and mills, the Cambria people have done much to improve the locality. The company's stores, run under the name of Wood, Morrell & Co., the original projectors of the iron-works, are themselves a substantial monument to the business importance of the place. I was told that in one month the sales amounted to $93,000—a goodly sum for a place of this size; but, as a rule, the miners and iron-workers are an improvident set, and enjoy their money while they have it. This accounts, in a measure, for the enormous sales of a store which must compete with many other well-stocked houses. It is, perhaps, an unequal competition; for, while the laws of the State forbid manufacturing and mining companies from paying their employés in merchandise, yet, in most cases, some pressure is brought to bear to influence the workmen's choice of stores. Adjoining the stores, one finds a large, substantial brick building, and on inquiry is told that it is the general offices and drawing-rooms of the company. On the opposite side of the street, another large brick building attracts the attention; it is the library erected by the company for the use of its employés and the townspeople generally. Its architecture and general appearance proclaim it to be a new structure; and if it fulfills the promise of its exterior, the Johnstownians can have no lack of good reading matter. It is a noticeable and very pleasing fact in all these industrial towns to see the pains the large companies are taking to furnish every incentive to their workmen to educate and cultivate themselves; and both by libraries and night-schools, the good work is helped along. At Johnstown, certain evenings in the week are devoted to lectures on various subjects of educational interest. Thus, the assistant mining engineer lectures on geology, another gentleman on astronomy, perhaps, and so on. The time seems finally to have come when capitalists recognize the importance of intelligent workmen, and, joining philanthropy and self-interest, they are making earnest efforts for the improvement of their employés. A few squares from the library, another building of no small pretensions is found in the Cambria Club-House, which addresses itself to the more material wants of Cambria's richer workmen. A few years since, and the visiting president and directors of the company had, in the absence of any decent hotels, to be accommodated at the house of the general manager; but since the gentlemen came once a month and staid several days on each visit, it became necessary to provide some more extensive quarters than could be demanded of individual hospitality, and so the Club-House was built to meet this requirement. Its advantages are, however, open to the company's employés, and to any strangers procuring cards of admission from officials high in authority. Unfortunately, the prices, ranging from thirty to sixty dollars a month for room and board, are beyond the means of most young men whom it would benefit—those coming from comfortable homes, who are ill prepared to be content at a country hotel or provincial boarding-house. The building is quite modern, having gas and electric bells, and is furnished in a modestly artistic style. The rooms are gems of their kind, having large windows, open grates, and Queen Anne furniture. On the whole, the entire building, inside and out, gives one the impression of being a well-kept, comfortable sort of place.

Nor is the town devoid of amusements. Though the largest building, Union Hall, affords but meager accommodation, in either auditorium or stage appointments, it is made the most of, and many a strolling dramatic company lures the half-dollar necessary for admittance to the "show" from the open pockets of the too careless workmen. At the time of our visit, Miss Pixley was in town, and with her company gave *M'liss* at the Hall. The performance was highly appreciated, the applause being quite uproarious at all sensational situations. The heavy villainy and wholesale display of revolvers particularly pleased the fancy of the iron-workers.

Not less conspicuous among Johnstown's buildings are her churches. A stranger is surprised to see such roomy and substantial structures. All denominations seem represented, and, from the size of their buildings, are apparently well patronized. Sunday morning finds quite a change in the town. The noise and bustle of the week are hushed, and the works, except the blast-furnaces, are at rest and silent. The Episcopal church, one of the prettiest in the place, gathered a very fair congregation to hear the discourse of her bishop. In the evening, we went a second time; but on account of the administration of confirmation, the church was greatly crowded, and we turned away to attend a neighboring service. We were somewhat amused to find the sermon about half over, but understood the cause when we afterward learned that the hour was a half earlier than in our own church.

With Monday morning, the stir and bustle of the place again manifested itself. Mills and shops were again in operation, and the town reverted to its condition of the previous week—that of a huge factory. Steel rails form the chief product of the company's works. The rail-mill is a long, low building, that presents many interesting features to a stranger. After watching the production of the pig-iron from the ores in the great blast-furnaces, and having seen the change of the pig metal into steel in the huge Bessemer converters, the last chapter in the transformation, the shaping of the steel into rails, is no less interesting. As carried out at present, the large ingots of metal, as they come from the converter, are heated to whiteness in furnaces, and having been rolled out into long bars, are cut into lengths such that each will form one rail. These smaller ingots are again reheated, and are now ready for the rolling-mill proper. Eleven times does the steel ingot pass through the rolls before it attains the proper shape for a rail. The mass of red-hot metal is first rolled into a short stout bar, then into a thinner but longer one, then into an approximation to the rail shape, and so on through the gradual changes, until it emerges into the perfect rail. But the process is not yet ended; for the rail ends are still ragged and uneven, and must be cut down to a smooth section and uniform length. To accomplish this, the rail, still red-hot, is brought before two parallel circular saws, revolving at great speed but without teeth. The distance between the saws being of the length desired for the rails, both ends are cut at once and the rail passes out to the cooling platform. Here small iron arms receive the rails, and placing them side by side, give to each a slight curve to allow for contraction. Were they left straight, they would be found to have a decided curve when cold, since there being a greater mass of metal in the head than in the flange, the contraction would be greater in the greater mass, and the rail would be found in a curve, with the flange on the outside. Hence the red-hot metal is curved with the head on the outside of the circle, so that when cold the rail shall be perfectly straight. When quite cold, the rails are further passed through another machine, so that any irregularities may be corrected, and the product be of perfect form.



Johnstown had many other objects of interest in the way of mines, wire-mills, and coking-ovens, at which we could take but a glance, and proceed on our pilgrimage; the Mecca of our trip being, in this case, Pittsburg. CARL.

THE STRAIGHT-LINE ENGINE.

We place before our readers illustrations of the straight-line engine, including special cuts of the latest improvements in the minor details which have never before appeared in print. The engine, as will be seen by an examination of the various engravings, differs in nearly every essential feature from all other engines heretofore brought out; and from the character of the design or the motto that we find on one of the circulars of the builders, "A straight line is the shortest distance between two points," we infer the name "straight line" was evolved.

The two sides of the frame run in straight lines following the lines of strain from the cylinder to the main bearings, and the frame, jacketed cylinder, steam-chest, guides, main bearings, etc., are cast in one piece and rest on three self-adjusting supports. All the lines in the design are straight, with curved ends, and all the sections rectangular, with rounded corners. While in its articulating and rotating elements there is very little that is essentially different from the modern horizontal engines, constructively each point has been a study in itself. The piston is very long and light, as shown by the section Fig. 1, and is secured to the rod by the double taper central thread and a shrink fit. The packing consists of four eccentric cast-iron rings sprung into grooves, and prevented from working around in the manner shown in Fig. 2; *A* being the piston, *B* the rings, and *C* filling pieces tightly driven in

THE STRAIGHT-LINE ENGINE.

the grooves. The joints between the ring and filling pieces are cut in such form that the expansion and contraction of the rings does not open a passage for steam between the two. The packing pieces are placed on the bottom of the piston, and dressed smooth, restoring the wearing surface to its full extent. The pistons are deeply recessed, to admit of the long Babbitt bushings which serve as the piston-rod packings *D*, Fig. 1. These bushings are self-adjusting, by the ball-and-socket and sliding joint, so as to conform to the position of the piston-rod, and are steam-tight when the engine is running, while they are four one thousandths of an inch loose on the rod. This is due to the length of the bush, the steam not having time to insinuate its way through the narrow opening during the time the engine is making a half-revolution. The piston-rod is secured in the cross-head by being threaded in between two half-nuts and the half-nuts clamped on the thread by binding screws. The cross-head pin is made fast in the connecting-rod by a clamp-bolt, and turns in the cross-head, giving two bearings in the place of one, as usually employed, with the advantage that the journals can be oiled with perfect convenience. The pin is of hardened steel, ground and polished, and turns in Babbitt bearings with effective compensating wedges and screws. The connecting-rods, Fig. 7, are of cast-steel, 6½ cranks long, and grasp the crank-pins more than one half the diameter of the cylinder in size and of a length equal to about one third the stroke of the engine. These crank-pins take direct hold of and join two fly-wheels. These wheels may be used for driving belts, or pulleys may be placed on the ends of the shafts, which project through the side frames for that purpose. (See Fig. 3.) The crank-pins and shafts are of steel, ground and polished in their bearings, and turn in compressed and scraped Babbitt-metal boxes.

One of the fly-wheels carries the governor, Fig. 4, which consists of a single governing weight, a single spring connected by links to a single shifting eccentric. The eccentric has cast with it two projecting arms, one being pivoted to the fly-wheel and the other attached to the governor. The weight of the governing ball is such as to just counterbalance the weight of the eccentric and its attachments against gravity; but the center of gravity of the weight being farther from the center of rotation than the eccentric, the weight being heavy, rotating in a large circle and at a high velocity, gives it high governing power. All the pivots subject to heavy strain are anti-friction journals, flat pieces of hardened steel rolling on round pins, giving rolling in the place of sliding contact, and requiring no oil.

The eccentric plate is pivoted in such a position that the engine when taking steam at three-quarter stroke has a positive lead; and when cutting off shorter, the lead changes to zero and negative lead, as the cut-off grows shorter and shorter.

One of the most novel features of the engine is the valve motion, which, though consisting of the ordinary rock-shaft arrangement, is so proportioned that the lead varies alike at each end of the cylinder, and the cut-off is practically alike at each end at all points of cut-off. This is accomplished by the position of the upper rocker-arm, which is at an acute angle with the eccentric-rod, as shown by the diagram Fig. 9. By this arrangement, the eccentric can be shifted when the crank is on either dead-center from its greatest to its least throw, without giving motion to the valve, if it is desirable to provide for a constant lead; or so as to give equal motion to the valve at each end when a variable lead is required. The rocker-arm is of ordinary construction, except that the lower arm is forked so as to take hold of each side of a sliding block which works in jaws on the end of the valve-rod, Fig. 5. The valve-rod works through a long Babbitt bush, which is secured in the frame of the engine by a taper fit and nut. The adjustable coupling on the valve-rod hooks into lugs cast on the valve in such a way that the valve may be removed without disturbing the adjustment. The valve is a flat slide working between a cover-plate and the valve-face, and distance-pieces between the valve-face and cover-plate above and below the valve, three or four one thousandths of an inch wider than the thickness of the valve, receive the full pressure of the steam on the cover-plate, allowing the valve to play free and yet practically steam-tight. Valves of this character were used in England years ago, and proved defective from two causes: First, the pressure-plates were too light, springing down and grasping the valve under high-pressure steam, and away from the valve and leaking under low pressure; and secondly, the exhaust steam issuing from the ports cut away the opposite faces on the cover-plate. In these engines, shields are cast in the valves, to protect the cover-plates from such action, and the cover-plates are made so strong that steam pressure does not spring them beyond the limit of clearance.

The throttle-valve is a disk rotating on a circular face, both the disk and face having a D-shaped opening on one side and a D-shaped recess in their faces opposite. When the two holes coin-

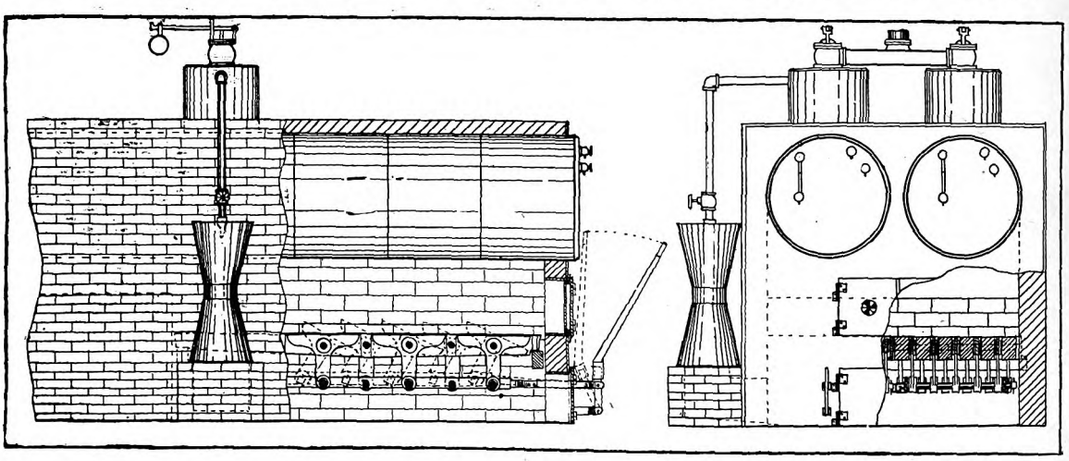
cide, there is a straight-way passage for the steam; and when the disk is turned half-way around, the valve is closed, and the recesses coming opposite, and being the same form as the openings, there is no face left exposed to rust. The engines are always to be run with an open throttle.

The material used in these engines is of the best quality obtainable, and the workmanship in all respects first class. They are run at medium or high speed, are so perfectly balanced as to run perfectly still on a solid foundation without holding-down bolts, and govern within the lowest fraction of variation, from full load to no load, and at all variations of steam pressure. All parts can be oiled from a common oil-can while in motion. The engine is built and sold in the West and Northwest by the M. C. Bullock Manufacturing Company, of Chicago; and for the Eastern, Middle, and Southern States by the Straight-Line Engine Company, of Syracuse,



ON THE MAGNETIZATION OF IRON AND STEEL.—Sir William Thomson, at a meeting of the British Association, read a communication from Mr. J. E. Ewing on the Susceptibility and Retentiveness of Iron and Steel. The author said that he had been experimenting in Japan on the effect of stress in relation to magnetization, and he had demonstrated the hitherto unsuspected fact that soft iron is capable of an immensely greater degree of magnetization than steel. The method employed was to subject wires to the magnetizing force, tapping them during its application, and withdrawing it gradually. When this plan was followed, 93 per cent of the charge remained. He had obtained magnetic intensity of 1590 units, while Thalen only obtained 40 from soft Swedish iron, and Roland 200. This result, Sir William Thomson said, was a satire on our knowledge of magnetism. The author also stated that he had computed the heating effect of the reversal of the induction in iron in absolute measure.

THE HOWE CULM GRATE.

The Howe culm grate, which is illustrated this week, consists of the ordinary grate-bars, cast with holes through them, through which rods are passed carrying knife-edged rockers, which are connected together and are rocked by means of a lever in front of the furnace. The grate-bars, spaces, and rockers are made equal width, and the bars are preferably made full length of furnace, and divided up so that the rockers are arranged to break joints, which prevents the fire being left in ridges. The holes in the bars and rockers are cored, and for burning culm or anthracite coal-dust, the bars, spaces, and rockers are each three eighths of an inch wide; for burning larger sizes of coal, the parts are made proportionally. Among the advantages claimed for this new grate are these: That culm, small-sized anthracite, and bituminous coal can be successfully burned and thoroughly cleaned on this grate, and make as much steam as large-sized coal; that it can be cleaned in two minutes without the use of the poker, and without loss of steam, as the furnace-doors are opened when feeding the fire; that it breaks up clinker and cinder by means of the knife-edge rockers, and forces them through the grate; that it has nearly sixty per cent air space, which insures good combustion; and that, as the bars are of simple construction, they are not likely to get out of order.

The engineers of the different departments of the Lackawanna Iron and Coal Company, by whom the grate has been used, speak of it in high terms. A series of experiments conducted by Mr. C. M. Morse, mechanical engineer, of this city, representative of the patentees, on the premises of Mrs. C. L. Weston, No. 332 Seventh avenue, gave the following results: In the boiler-room are two boilers, which, until recently, had been running with a Jarvis furnace setting, burning egg coal, the grate surface per furnace being 40 square feet, and the expenditure for fuel for the month of June being with the Jarvis setting $19.60 per day. One furnace was then equipped with the Howe grate and a steam-blower, the supplementary air-ducts of the Jarvis setting being bricked up. One furnace, with hard firing, could furnish steam enough for a 150 horse-power engine, and the two were therefore alternately used to do that duty. On one day, the furnace equipped with the Howe grate and blower consumed 4315 pounds of Lackawanna culm at $2.35 per ton, and 1230 pounds of bituminous coal at $4.55 per ton, the total cost of fuel for the day being $7.02. On the next day, the other boiler, left unchanged, used 5234 pounds of egg coal at $4.95 per ton, a daily cost of $11.56, thus showing a saving in the cost in favor of the Howe grate of $4.54 per day. Both boilers together, on the following day connected, supplied steam for the engine and all other purposes, using 4072 pounds of egg at $4.95, 3672 pounds of culm at $2.35 per ton, and 133 pounds of bituminous coal at $4.55, making the total cost per day $13.12, against the average of $19.60 in June.

GASES OCCLUDED BY COKE.—A recent number of the *American Chemical Journal* gives some interesting details of an exhaustive series of experiments on the gases occluded by coke, carried out by Messrs. F. H. Storer and D. H. Lewis. Reichardt's method of exhausting with mercury and heating was used, but only to compare the results given by it with those afforded by the Sprengel pump; the flask containing the coke being exhausted and subsequently heated in a paraffine bath. The first experiments were made upon some air-dried coke from the cellar of a dwelling-house. The maximum temperature to which it was subjected was, as in all other cases, 200 degrees Fahr. By Reichardt's method, each gram of coke gave rather more than 1 c. c. of gas containing about 43 per cent of carbonic acid and 2·6 per cent of oxygen. With the Sprengel pump, each gram yielded about 0·7 c. c. of gas containing from 50 to 60 per cent of carbonic acid and from 2 to 6 per cent of oxygen, as well as carbonic oxide and nitrogen. In some cases where the pump was used, a current of nitrogen was driven through the flask for some time, to clear out the air more effectually. Some air-dried coke, which had been standing for two years in a dry storehouse, gave (by Reichardt's method) about the same quantity of gas as the above; the percentage of carbon dioxide being lower, and that of nitrogen and oxygen much higher. The same coke, however, with the pump gave less gas; but the percentage of carbonic acid was higher, and that of oxygen lower than in the first samples. Other experiments with old coke from out of doors, recently partially dried coke, and coke taken straight from a gas-retort gave results very similar, save that, in the last case, the percentage of carbonic acid, which was at first only between 7 and 11 per cent, increased (on keeping for two months) to 21 per cent. It would thus almost seem as if a slow oxidation of the carbon had gone on. It is noteworthy that the gases given off up to 100 degrees Fahr. invariably contained a higher percentage of oxygen, and a lower one of carbonic acid, than those by heating to 200° Fahr.

A PLEA FOR PURE SCIENCE.*†

American science is a thing of the future, and not of the present or past; and the proper course of one in my position is to consider what must be done to create a science of physics in this country, rather than to call telegraphs, electric lights, and such conveniences, by the name of science. I do not wish to underrate the value of all these things; the progress of the world depends on them, and he is to be honored who cultivates them successfully. So also the cook who invents a new and palatable dish for the table benefits the world to a certain degree; yet we do not dignify him by the name of a chemist. And yet it is not an uncommon thing, especially in American newspapers, to have the *applications* of science confounded with pure science; and some obscure American who steals the ideas of some great mind of the past, and enriches himself by the application of the same to domestic uses, is often lauded above the great originator of the idea, who might have worked out hundreds of such applications, had his mind possessed the necessary element of vulgarity. I have often been asked, which was the most important to the world, pure or applied science? To have the applications of a science, the science itself must exist. Should we stop its progress, and attend only to its applications, we should soon degenerate into a people like the Chinese, who have made no progress for generations, because they have been satisfied with the applications of science, and have never sought for reasons in what they have done. The reasons constitute pure science. They have known the application of gunpowder for centuries; and yet the reasons for its peculiar action, if sought in the proper manner, would have developed the science of chemistry, and even of physics, with all their numerous applications. By contenting themselves with the fact that gunpowder will explode, and seeking no farther, they have fallen behind in the progress of the world; and we now regard this oldest and most numerous of nations as only barbarian. And yet our country is in this same state. But we have done better; for we have taken the science of the old world, and applied it to all our uses, accepting it like the rain of heaven, without asking whence it came, or even acknowledging the debt of gratitude we owe to the great and unselfish workers who have given it to us. And, like the rain of heaven, this pure science has fallen upon our country, and made it great and rich and strong.

To a civilized nation of the present day, the applications of science are a necessity; and our country has hitherto succeeded in this line, only for the reason that there are certain countries in the world where pure science has been and is cultivated, and where the study of nature is considered a noble pursuit. But such countries are rare, and those who wish to pursue pure science in our own country must be prepared to face public opinion in a manner which requires much moral courage. They must be prepared to be looked down upon by every successful inventor whose shallow mind imagines that the only pursuit of mankind is wealth, and that he who obtains most has best succeeded in the world. Everybody can comprehend a million of money; but how few can comprehend any advance in scientific theory, especially in its more abstruse portions! And this, I believe, is one of the causes of the small number of persons who have ever devoted themselves to work of the higher order in any human pursuit. Man is a gregarious animal, and depends very much for his happiness on the sympathy of those around him; and it is rare to find one with courage to pursue his own ideas in spite of his surroundings. In times past, men were more isolated than at present, and each came in contact with a fewer number of people. Hence that time constitutes the period when the great sculptures, paintings, and poems were produced. Each man's mind was comparatively free to follow its own ideals, and the results were the great and unique works of the ancient masters. To-day, the railroad and the telegraph, the books and newspapers, have united each individual man with the rest of the world; instead of his mind being an individual, a thing apart by itself and unique, it has become so influenced by the outer world, and so dependent upon it, that it has lost its originality to a great extent. The man who in times past would naturally have been in the lowest depths of poverty, mentally and physically, to-day measures tape behind a counter, and with lordly air advises the naturally born genius how he may best bring his outward appearance down to a level with his own. A new idea he never had, but he can at least cover his mental nakedness with ideas imbibed from others. So the genius of the past soon perceives that his higher ideas are too high to be appreciated by the world; his mind is clipped down to the standard form; every natural offshoot upward is repressed, until the man is no higher than his fellows. Hence the

* Abstracts from an address of H. A. Rowland, of Baltimore, Md., Vice-President of Section B, American Association for the Advancement of Science.

† In using the word "science," I refer to physical science, as I know nothing of natural science. Probably my remarks will, however, apply to both, but I do not know.

Digitized by Google

world, through the abundance of its intercourse, is reduced to a level. What was formerly a grand and magnificent landscape, with mountains ascending above the clouds, and depths whose gloom we can not now appreciate, has become serene and peaceful. The depths have been filled, and the heights leveled, and the wavy harvests and smoky factories cover the landscape.

As far as the average man is concerned, the change is for the better. The average life of man is far pleasanter, and his mental condition better, than before. But we miss the vigor imparted by the mountains. We are tired of mediocrity, the curse of our country. We are tired of seeing our artists reduced to hirelings, and imploring Congress to protect them against foreign competition. We are tired of seeing our countrymen take their science from abroad, and boast that they here convert it into wealth. We are tired of seeing our professors degrading their chairs by the pursuit of applied science instead of pure science; or sitting inactive while the whole world is open to investigation; lingering by the wayside while the problem of the universe remains unsolved. We wish for something higher and nobler in this country of mediocrity, for a mountain to relieve the landscape of its monotony. We are surrounded with mysteries, and have been created with minds to enjoy and reason to aid in the unfolding of such mysteries. Nature calls to us to study her, and our better feelings urge us in the same direction. . . .

There is room for all in the work, and the race has but commenced. The problems are not to be solved in a moment, but need the best work of the best minds, for an indefinite time.

Shall our country be contented to stand by, while other countries lead in the race? Shall we always grovel in the dust, and pick up the crumbs which fall from the rich man's table, considering ourselves richer than he because we have more crumbs, while we forget that he has the cake, which is the source of all crumbs? Shall we be swine, to whom the corn and husks are of more value than the pearls? If I read aright the signs of the times, I think we shall not always be contented with our inferior position. From looking down, we have almost become blind, but may recover. In a new country, the necessities of life must be attended to first. The curse of Adam is upon us all, and we must earn our bread.

The scientific study of nature in all its branches, of mathematics, of mankind in its past and present, the pursuit of art, and the cultivation of all that is great and noble in the world—these are the highest occupations of mankind. Commerce, the applications of science, the accumulation of wealth, are necessities which are a curse to those with high ideals, but a blessing to that portion of the world which has neither the ability nor the taste for higher pursuits.

As the applications of science multiply, living becomes easier, the wealth necessary for the purchase of apparatus can better be obtained, and the pursuit of other things besides the necessities of life becomes possible.

But the moral qualities must also be cultivated in proportion to the wealth of the country, before much can be done in pure science. The successful sculptor or painter naturally attains to wealth through the legitimate work of his profession. The novelist, the poet, the musician, all have wealth before them as the end of a successful career. But the scientist and the mathematician have no such incentive to work; they must earn their living by other pursuits, usually teaching, and only devote their surplus time to the true pursuit of their science. And frequently, by the small salary which they receive, by the lack of instrumental and literary facilities, by the mental atmosphere in which they exist, and, most of all, by their low ideals of life, they are led to devote their surplus time to applied science or to other means of increasing their fortune. How shall we, then, honor the few, the very few, who, in spite of all difficulties, have kept their eyes fixed on the goal, and have steadily worked for pure science, giving to the world a most precious donation, which has borne fruit in our greater knowledge of the universe and in the applications to our physical life which have enriched thousands and benefited each one of us? There are also those who have every facility for the pursuit of science, who have an ample salary and every appliance for work, yet who devote themselves to commercial work, to testifying in courts of law, and to any other work to increase their present large income. Such men would be respectable if they gave up the name of professor, and took that of consulting chemists or physicists. And such men are needed in the community. But for a man to occupy the professor's chair in a prominent college, and, by his energy and ability in the commercial applications of his science, stand before the local community in a prominent manner, and become the newspaper exponent of his science, is a disgrace both to him and his college. It is the death-blow to science in that region. Call him by his proper name, and he becomes at once a useful member of the community. Put in his place a man who shall by precept and example cultivate his science, and how different is the result! Young men, looking forward into the world for something to do see before them this high and noble life, and they see that there is something more honorable than the accumulation of wealth. They are thus led to devote their lives to similar pursuits, and they honor the professor who has drawn them to something higher than they might otherwise have aspired to reach.

I do not wish to be misunderstood in this matter. It is no disgrace to make money by an invention, or otherwise, or to do commercial scientific work under some circumstances. But let pure science be the aim of those in the chairs of professors, and so prominently the aim that there can be no mistake. If our aim in life is wealth, let us honestly engage in commercial pursuits, and compete with others for its possession. But if we choose a life which we consider higher, let us live up to it, taking wealth or poverty as it may chance to come to us, but letting neither turn us aside from our pursuit.

The work of teaching may absorb the energies of many; and indeed, this is the excuse given by most for not doing any scientific work. But there is an old saying, that where there is a will there is a way. Few professors do as much teaching or lecturing as the German professors, who are also noted for their elaborate papers in the scientific journals. I myself have been burdened down with work, and know what it is; and yet I here assert that all *can* find time for scientific research if they desire it. But here, again, that curse of our country, mediocrity, is upon us. Our colleges and universities seldom call for first-class men of reputation, and I have even heard the trustee of a well-known college assert that no professor should engage in research because of the time wasted! I was glad to see, soon after, by the call of a prominent scientist to that college, that the majority of the trustees did not agree with him.

That teaching is important, goes without saying. A successful teacher is to be respected; but if he does not lead his scholars to that which is highest, is he not blameworthy? We are, then, to look to the colleges and universities of the land for most of the work in pure science which is done. Let us, therefore, examine these latter, and see what the prospect is. . . .

I have before me the report of the Commissioner of Education for 1880. According to that report, there were 389,* or say, in round numbers, 400 institutions, calling themselves colleges or universities, in our country! We may well exclaim that ours is a great country, having more than the whole world besides. The fact is sufficient. The whole earth would hardly support such a number of first-class institutions. The curse of mediocrity must be upon them, to swarm in such numbers. They must be a cloud of mosquitoes, instead of eagles as they profess. And this becomes evident on further analysis. About one third aspire to the name of university; and I note one called by that name which has two professors and 18 students, and another having three teachers and 12 students! And these instances are not unique, for the number of small institutions and schools which call themselves universities is very great. It is difficult to decide from the statistics alone the exact standing of these institutions. The extremes are easy to manage. Who can doubt that an institution with over 800 students, and a faculty of 70, is of a higher grade than those above cited having 10 or 20 students and two or three in the faculty? Yet this is not always true; for I note one institution with over 500 students which is known to me personally as of the grade of a high-school.

If the statistics were forthcoming—and possibly they may exist—we might also get an idea of the standing of these institutions and their approach to the true university idea, by the average age of the scholars. Possibly also the ratio of number of scholars to teachers might be of some help. All these methods give an approximation to the present standing of the institutions. But there is another method of attacking the problem, which is very exact, but it only gives us the *possibilities* of which the institution is capable. I refer to the wealth of the institution. In estimating the wealth, I have not included the value of grounds and buildings; for this is of little importance either to the present or future standing of the institution. As good work can be done in a hovel as in a palace. I have taken the productive funds of the institution as the basis of estimate. I find:

284	have below	$500,000.
8	" between	$500,000 and $1,000,000.
8	" over	$1,000,000.

There is no fact more firmly established, all over the world, than that the higher education can never be made to pay for itself. Usually, the cost to a college of educating a young man very much exceeds what he pays for it, and is often three or four times as much. The higher the education, the greater this proportion will be; and a university of the highest class should anticipate only a small accession to its income from the fees of students. Hence the test I have applied must give a true representation of the possibilities in every case. According to the figures, only sixteen colleges and universities have $500,000 or over of invested funds, and only one half of these have $1,000,000 and over. Now, even the latter sum is a very small endowment for a college; and to call any institution a university which has less than $1,000,000 is to render it absurd in the face of the world. And yet more than one hundred of our institutions, many of them very respectable colleges, have abused the word "university" in this manner. It is to be hoped that the endowment of the more respectable of these institutions may be increased, as many of them deserve it; and their unfortunate appellation has probably been repented of long since.

It may be urged, that all these institutions are doing good work in education; and that many young men are thus taught who could not afford to go to a true college or university. But I do not object to the education—though I have no doubt an investigation would disclose equal absurdities here—for it is aside from my object. But I do object to lowering the ideals of the youth of the country. Let them know that they are attending a school, and not a university; and let them know that above them comes the college, and above that the university. Let them be taught that they are only half-educated, and that there are persons in the world by whose side they are but atoms. In other words, let them be taught the truth.

It may be that some small institutions are of high grade, especially those which are new; but who can doubt that more than two thirds of our institutions calling themselves colleges and universities are unworthy of the name? Each one of these institutions has so-called professors, but it is evident that they can be only of the grade of teachers. Why should they not be so called? The position of teacher is an honored one, but it is not made more honorable by the assumption of a false title. Furthermore, the multiplication of the title, and the ease with which it can be obtained, render it scarcely worth striving for. When the man of energy, ability, and perhaps genius, is rewarded by the same title and emoluments as the commonplace man with the modicum of knowledge, who takes to teaching not because of any aptitude for his work, but possibly because he has not the energy to compete with his fellow-men in business, then I say one of the inducements for first-class men to become professors is gone.

When work and ability are required for the position, and when the professor is expected to keep up with the progress of his subject, and to do all in his power to advance it, and when he is selected for these reasons, then the position will be worth working for, and the successful competitor will be honored accordingly. The chivalric spirit which prompted Faraday to devote his life to the study of nature may actuate a few noble men to give their life to scientific work; but if we wish to cultivate this highest class of men in science, we must open a career to them worthy of their efforts.

Jenny Lind, with her beautiful voice, would have cultivated it to

* 364 reported on, and 25 not reported.

Digitized by Google

some extent in her native village; yet who would expect her to travel over the world, and give concerts for nothing? and how would she have been able to do so if she had wished? And so the scientific man, whatever his natural talents, must have instruments and a library, and a suitable and respectable salary to live upon, before he is able to exert himself to his full capacity. This is true of advance in all the higher departments of human learning, and yet something more is necessary. It is not those in this country who receive the largest salary, and have positions in the richest colleges, who have advanced their subject the most; men receiving the highest salaries, and occupying the professor's chair, are to-day doing absolutely nothing in pure science, but are striving by the commercial applications of their science to increase their already large salary. Such pursuits, as I have said before, are honorable in their proper place; but the duty of a professor is to advance his science, and to set an example of pure and true devotion to it which shall demonstrate to his students and the world that there is something high and noble worth living for. Money-changers are often respectable men, and yet they were once severely rebuked for carrying on their trade in the court of the temple.

Wealth does not constitute a university, buildings do not; it is the men who constitute its faculty, and the students who learn from them. It is the last and highest step which the mere student takes. He goes forth into the world, and the hight to which he rises has been influenced by the ideals which he has consciously or unconsciously imbibed in his university. If the professors under whom he has studied have been high in their profession, and have themselves had high ideals; if they have considered the advance of their particular subject their highest work in life, and are themselves honored for their intellect throughout the world, the student is drawn toward that which is highest, and ever after in life has high ideals. But if the student is taught by what are sometimes called good teachers, and teachers only, who know little more than the student, and who are often surpassed and even despised by him, no one can doubt the lowered tone of his mind. He finds that by his feeble efforts he can surpass one to whom a university has given its highest honor; and he begins to think that he himself is a born genius, and the incentive to work is gone. He is great by the side of the molehill, and does not know any mountain to compare himself with.

A university should not only have great men in its faculty, but have numerous minor professors and assistants of all kinds, and should encourage the highest work, if for no other reason than to encourage the student to his highest efforts.

But, assuming that the professor has high ideals, wealth such as only a large and high university can command is necessary to allow him the fullest development.

(TO BE CONTINUED.)

FURNACE, MILL AND FACTORY.

The New York, Pennsylvania & Ohio Railroad Company, after having tested the Brown hoisting and conveying machine by using, during two seasons, a plant consisting of three machines suspended on cable tramways, ordered an additional plant for its ore-dock in Cleveland. This plant, consisting of three machines with truss-bridge tramways, hoist-house, and hoisting appliances, is now receiving the finishing touches, and will perhaps be in operation by the time this reaches the readers of the ENGINEERING AND MINING JOURNAL. The bridges are each 180-foot span, the ends being supported on piers which rest on a track to which they are firmly held by a simple device, and on which the tramways are movable along the line of the dock. A ball-and-socket joint enables the workmen to adjust the front pier to the hatch of a vessel without moving the rear pier. In and between the back piers of two of the three bridges are the hoist-house and machinery, consisting of a locomotive boiler 16 feet long, 48 inches shell, and three double-acting four-inch cylinder hoisting-drums (Webster, Camp & Lane Machine Company's make), one of which is arranged at a right angle with the other two and with the line of movement of the piers, so as to allow the one bridge to be moved independently of the other two, which are connected and contain the hoist plants. All of it moves together, and can be driven along the track by one man at each pier turning the crank of the gearing arranged for that purpose. The bridges and piers present a very neat appearance. The trusses are of the inverted parabolic bow-string type, and the size and position of each part are designed and calculated with mathematical precision with reference to the duty each has to perform, a large allowance being made for safety. As the machine and bucket works within the space occupied by the truss, and the hight of clearance is the maximum hight of ore that the dock can safely sustain, the full width of the dock can be filled by the machine operated by one man in the hoist-house. The size of bucket used is one gross ton capacity, and the speed in handling is only limited by the rapidity with which the men on the vessel can fill the buckets. Great care has been taken to provide against any special strain or wear, and all emergencies of operating, even to providing to a great extent against the carelessness and cupidity usual to thoughtless or unprincipled workmen. The Brown Hoisting and Conveying Machine Company is about to bring to public notice a new and automatic system for charging blast-furnaces, ovens, kilns, etc., the first cost of which is cheaper. It does away with all top fillers, present style of hoist-house, etc., making it possible for one man easily to accomplish the whole work by operating an engine and accompanying mechanical arrangements. The system is the invention of Mr. Fayette Brown, and the details of construction and operation are by Alexander E. Brown. It has been tested by continuous service for a year or more at one of the most successful furnaces of the country, and already several large concerns have placed their orders for similar outfits.

Best & Gibson, furnace builders, St. Louis, have recently erected three annealing furnaces and two ovens for the Ashley Wire Company, Joliet, Ill., and have another contract for the same company for the building of seven more annealing furnaces and a muffle-furnace.

The articles of association of the Kalamein Alloy Company, Limited, were filed for record in Pittsburg on the 25th ult. The total amount of capital stock is $500,000, of which $460,000 have been paid in, that sum being paid to the owners for certain patent rights under which the company proposes to operate. The business of the company is to be the manufacture, use, and sale of the inventions mentioned, and the stockholders are the following gentlemen, each of whom owns the amount stated: Henry W. Shepard, $230,000; H. W. Oliver, Jr., $40,000; D. B. Oliver, $40,000; J. B. Oliver, $40,000; George T. Oliver, $40,000; Henry Roberts, $40,000; and Cadwallader Evans, $30,000. The kalamein alloy is a substance invented by Mr. Henry Roberts, who has devised a process to be substituted for galvanizing.

The Steelton *Reporter*, 27th ult., says: No. 2 furnace was not damaged to so great an extent as we thought it was from the explosion on Friday of last week. The repairs were completed and the blast and a cast made in five hours afterward. The furnace has been doing good work all the week. No. 5 furnace produced 27 tons of pig-iron one day this week, being the largest product ever obtained from "Little Dock." Masons are at work on the stone foundations for the new hot ovens at No. 1 furnace. The basic mill has been running successfully and increasing in production. The large rolls at the new merchant mill will be put into operation on Wednesday or Thursday. All the machinery has been tested and found to be in good working order, and the successful starting of the new mill is anxiously looked for. Mr. E. C. Felton was in Tyrone this week, witnessing the rolling of steel skelp from the basic mill. The steel is used for making boiler tubes, and is found especially fine for that purpose, being easily rolled and welding nicely.

The Link-Belt Machinery Company, of Chicago, has recently filled orders as follows: The Lead Mine Company, of Bingham, Utah, an ore-conveyer; the Columbus & Hocking Coal and Iron Company, Columbus, O., a 40-foot coal-elevator; the Boston Gas-Light Company, of Boston, a 75-foot double-strand coal-elevator; the Abbey Coal Mining Company, St. Louis, Mo., a coal-elevator; Wells, Fargo & Co., at Salt Lake City, an ore-elevator, to be used in a mine.

John H. Davey, of Galena, Dakota, is putting in a Gates pulverizer from the works of Charles Kaestner & Co., Chicago, and S. L. Bailey and Robert Seaman have ordered one to go to their Wyoming mines. The manufacturers state that they are ready to guarantee 40 tons a day through a 40-mesh screen, with 15 horse-power. The machine takes up a floor-space of 11 by 6 feet, and weighs 18,000 pounds.

The famous Société John Cockerill, of Belgium, has, according to an annual report just published, established an agency in this city.

The property of the Norwood Lumber Company was sold at auction in Norwood, N. Y., November 7th, to A. O. Brainerd, of St. Alban's, Vt., for $166,500.

The Ohio Iron and Steel Company, operating the Mary furnace at Lowellville, has just completed the erection of a large iron casting-house. This, with the improvements made the past season, makes it one of the finest iron plants in the Mahoning Valley.

The sheriff's sale of the Huntington Car-Works property was held recently, and lasted several days. Forty-five creditors were present, whose aggregate claims amounted to $350,000. Considerable litigation is expected before a final adjustment of the claims is made.

Under an order of the Supreme Court in Equity, at St. John, N. B., on November 5th, there was offered at auction the Coldbrook iron-works and rolling-mill and the Coldbrook nail and spike factory. The properties, which were sold together, were knocked down for $32,000 to the Maritime Bank of the Dominion of Canada.

H. G. Lapham & Co. have placed their order with the Lechner Manufacturing Company, Columbus, O., for chain elevators and conveyers, to be used in their tannery at Tunkhannock, Pa., for conveying dry and spent tan. The Lechner Company has also received orders for chain belting from Samuel Williamson, of Cincinnati, Phœnix Iron-Works, Meadville, Pa., and others, to be used for driving purposes.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY—TOMBSTONE DISTRICT.

BOSTON & ARIZONA SMELTING AND REFINING COMPANY.—The starting up of these reduction-works and the resumption of work at the Stonewall mine are announced.

CONTENTION.—It is reported that a new body of ore has been struck while prospecting in a northeasterly direction.

EMPIRE.—The new shaft is down 45 feet. This shaft is to tap the ore-body which extends from the Good Enough and Way Up mines. The rock has changed from lime into porphyry heavily stained with iron. In the old workings, the timbering has been completed, and brisk prospecting from the 200 and 400-foot levels is going on. A cross-cut east from the 400 foot level is running, and is at present in a very hard limestone.

GILDED AGE.—This mine has been sold to the owners of the Way Up mine. Underground surveys are making with the intention of starting work on the mine.

MAMIE.—Considerable work in the upper levels of this mine is doing. The lessees have just completed a shipment to the Watervale mill of nine tons of ore that samples $67 to the ton.

PROMPTER.—An assessment of ten cents per share has been levied, the money to be used for the erection of hoisting-works.

SAN PEDRO.—This mine has been leased.

PIMA COUNTY.

It is stated that a smelter will be erected at Tucson very shortly. Mr. Aaron Mason, who is interested in the enterprise, is in Tucson, attending to the preliminary arrangements. A thirty-ton smelter will first be put up. Power will also be put in at same time for a copper smelter. Copper will be bought from the start. With the smelter, there will also be sampling-works and concentrating-tables.

PINAL COUNTY.

RAY COPPER.—The superintendent reports, October 29th: Developments continue very favorable. North drift, 50-foot level, now in 45 feet, still in heavy native copper—sheet-copper, but increasing in thickness of the sheet. Cross-cut, 100-foot level, in 26 feet, also in native copper and carrying considerable glance with the native. Winze No. 3 from station 100-foot level, now down 31 feet; carrying considerable glance for the past three days, and some oxide. The native lies to the northwest. At 50 feet, we shall put in another station, then cross-cut and drift for the native. Our ore in this winze (copper glance) has assayed as high as 62 per cent. No. 1 shaft will be put in position at once. I have put a steam-pump on the well, to enable the men to continue sinking the same to the bed-rock.

SILVER BOW COUNTY.

The Anaconda Company has made arrangements with the Union Pacific for the extension of a branch line connecting Stuart Station, on the Utah & Northern, with the town of Anaconda. It is understood that the work of construction will begin at once, and that by the first of December the branch will be completed and in operation. In addition to this branch, the Union Pacific Company has agreed at once to begin the construction of a second branch from the present terminus of the road at the Montana smelter, to the St. Lawrence and Anaconda mines. The road-bed and ties will be broad-gauge, and the track for the present will be narrow-gauge. The conditions of the contract are, that the Anaconda Company is to procure the right of way, and that the Union Pacific Company will consent at any time to the laying of a third rail on the branch by the Northern Pacific Company.

SUMMIT VALLEY DISTRICT.

COLUSA.—According to the *Inter-Mountain*, a private letter received from London states that the negotiations for the sale of this mine and plant to English capitalists have been almost concluded. The price, if the sale goes, is understood to be $1,500,000.

JOSEPHINE.—It is claimed that this is an extension of the Lexington. The ore-body varies in width from three to ten feet, and pulps in the mill about $45. Since operations on the mine were resumed a short time ago, 300 tons of ore have been hoisted, and worked in the Silver Bow mill.

LEXINGTON.—The company is opening up the Allie Brown, a vein which runs parallel with the main property. The shaft is now down 50 feet, all in ore, which mills 50 ounces.

POLLOCK.—This prospect is located east of the Poser. The claim contains two separate and distinct veins. Shafts have been sunk and a tunnel is running on one of the veins. A 100-ton lot has just been sent to the Moulton mill to be treated.

POSER.—The daily product averages 20 tons, which pulps in the Silver Bow mill about $35. The productive capacity of this mine is considered sufficient to supply a 40-stamp mill, and it is among the probabilities that the company next year will have reduction-works of its own.

WASHOE.—An important strike has been made at a depth of 212 feet.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

BODIE CONSOLIDATED.—During the week ended October 27th, 216 car-loads of ore were hoisted from the mine, 13 car-loads of which were from the 770 (shaft) level and 187 car-loads were from the stopes between the 640 and 780-foot levels. The remaining 66 car-loads were extracted from the old workings at the 206 and 306-foot levels. During the week, 163·535 tons of ore were hauled to the mill and 136·765 tons of ore were crushed. The average assay value of the pulp was $37.83 per ton; that of the tailings was $6.20 per ton.

STANDARD CONSOLIDATED.—There were extracted and shipped to the mills 1436 tons of ore during the week ended October 27th; received 1585 ounces of crude bullion. There is no change to notice in the appearance of the stopes.

PATERSON DISTRICT.

SUMMERS.—A new strike has been made in the lower tunnel. The ledge is six feet wide. The little five-stamp mill is running steadily, and cleaning up from $20,000 to $25,000 per month.

SWEETWATER.—The Great Western, Lookout, and other mines belonging to this group are looking well. Operations have been suspended pending negotiations for their purchase by a New York company. The mines are bonded to William Irwin, representing the Standard Company, of Bodie.

NEVADA COUNTY.

MAGENTA CONSOLIDATED.—The company has been reorganized. About nine years ago, a shaft was sunk to the depth of 365 feet, and about 1000 feet of drifts were run, but no stoping was done. The mine has been idle most of the time since; the company then owning the property not having sufficient capital to develop it. Work has now begun, and developments will be pushed vigorously.

YUBA COUNTY.

EXCELSIOR WATER AND MINING COMPANY.—This company has begun an action in the Superior Court to recover $266,692 from J. P. Pierce, of Santa Clara. The complaint alleges that defendant was a stockholder and director of said corporation, and that on nineteen different occasions between July, 1877, and September 22d, 1879, resolutions were adopted declaring dividends upon the shares of stock of said corporation, and that dividends were paid thereon at times when there were no surplus earnings or profit, and that, in fact, said dividends were drawn from the capital stock of said corporation; it also alleges that James P. Pierce was a director, and was present and voted for each of the resolutions declaring such dividends.

CANADA.

PROVINCE OF QUEBEC.

DOMINION PHOSPHATE AND MINING COMPANY.—A special meeting of the stockholders will be held at the company's office in Montreal, November 14th, for the purpose of considering the matter of increasing the stock of the company, and to decide whether the company shall accept or decline to purchase the property known as Lot No. 18, 7th Range, Township of Portland East, County and District of Ottawa, Province of Quebec.

COLORADO.

CHAFFEE COUNTY.

CLAREMONT.—The Red Mountain Mining Company began operations last year, but, falling into litigation, did not accomplish much. Its troubles have, however, been adjusted, the company dissolved, and the Claremont Mining and Milling Company is its successor. The company owns mining property in the Red Mountain District, including the Gibraltar and Bonanza lodes. A thirty-stamp mill will be erected soon.

TABOR VS. COLUMBUS.—The suit of the Tabor mining lode claimants against the Columbus Mining and Milling Company, on trial in the United States Court at Denver, has been decided in favor of the Tabor. The judgment awarded the plaintiffs the disputed ground and $4500 damages.

CLEAR CREEK COUNTY.

DIAMOND.—This tunnel is now 2188 feet in length. Much interest is taken in the developments lately made on the first intersection of the Corry City veins which this tunnel cuts at 2100 feet from its mouth. Thus far, four distinct and well-defined veins have been encountered, within a distance of 50 feet of cross-cutting. The other veins cut by this tunnel show small streaks of ore. The East Dives Company is working its property through this tunnel. Arrangements are making for extended workings in and through the tuunel and property. It has cost $1,000,000 to drive the tunnel, not taking into consideration other developments. The production up to the present time of the lodes cut by the tunnel is as follows: No. 5 and E. K. Baxter lode, $350,000; D. T. No. 6, $160,000; Pelican & Dives, over $2,000,000, besides considerable production from smaller veins.

DOLORES COUNTY.

NELLIE AND ELLA.—These mines have been sold for $50,000.

RICO REDUCTION COMPANY.—The company has purchased a half-interest in the Little Susie group of mines on the West Dolores, nine miles above the Fish Fork. The mines are the Little Susie, Little Wonder, Russian Bear, Democrat, and Governor Grant lodes, all near together.

GILPIN COUNTY.

COTTON.—This mine, situated on Bobtail Hill, has been sold for $25,000.

GUNNISON COUNTY.

DOMINGO.—This mine has been sold to Missouri capitalists for $20,000.

HINSDALE COUNTY.

CROOKE MINING AND SMELTING COMPANY.—No work will be done at the Ulé for an indefinite period except to keep down the water. The steam-power at the mine will be used to drive the concentrator. At the Ute, all the present forces will be continued and the mine driven to its full capacity. It it expected that enough ore will be taken from the Ute to keep both sides of the concentrator in operation.

HENSON CREEK REDUCTION COMPANY.—The concentrator has made several successful runs. The machinery worked well, but the water in the creek is growing visibly less, and it is feared that soon there will not be enough to run the mill. The smelter can be completed as soon as there is demand for it, and can be put in operation on sixty days' notice, all that is required being three thousand fire-brick and the erection of the blast-furnace, the columns and piping being on the ground.

SAN JUAN & WISCONSIN.—Work on the Lone Tree and Seventy-six lodes has begun. The company is securing patents on all its properties.

LAKE COUNTY.

A. Y.—The ore production is confined principally to the extraction of sulphide ores that formerly would not pay mining expenses, and at present smelting rates return only small profits.

CATALPA.—During October, the mine produced only a limited quantity of ore; and as a consequence, the profits are small. The manager stated that, notwithstanding this fact, he would be able to transmit to the company $1000 out of the ore receipts after paying the month's working expenses.

DENVER CITY & LEE BASIN.—These mines, on Yankee Hill, after a suspension of about nine months, are to be started up again. The properties consist of three full claims, and were first acquired by the present company in 1879. The strikes in the Dexter and Elkins shafts, just west of the Denver City and Lee Basin claims, have led to the resumption.

DUNKIN.—During October, 278 tons of ore were extracted and sold to the smelters, returning $6290.98; expenses, $3133.66; net profit, $1457.32.

HARRISON.—These works, after a suspension of about two months, have resumed operations.

HENRIETT.—Developments are now in progress which promise to result in valuable discoveries of ore. At a stockholders' meeting held in London, England, resolutions to wind up the company voluntarily, and appointing Mr. William A. Rose liquidator, were carried unanimously.

IRON HILL CONSOLIDATED.—This company has its machinery on the Imes shaft in good working condition. The developments contiguous to the Imes are preparing for active work, and in a short time, this portion of the property will be producing regularly. The workings of the Imes are still 120 feet distant from the farthest north drift of the White Cap, the nearest working-shaft of the same company. The two shafts will be connected as soon as possible. The production of the mines for October was in excess of the yield during the previous month, and the properties are looking well.

ST. BERNARD MINING COMPANY VS. LESSEES OF MOYAMENSING CLAIM.—Suits were filed in the District Court, at Leadville, November 3d, for over $500,000 damages. The suits were instituted by the St. Bernard Mining Company and the lessees of the Moyamensing claim, each of which sues for the recovery of $300,000, making a total of $600,000, which Messrs. Dennis Sullivan, James Dexter, and others, are expected to refund. The claim is based on the extraction of ore from the Moyamensing claim, which ore, it is alleged, was extracted from the Moyamensing claim and hoisted through the South May Queen and Dexter shaft. The suit is one of the largest yet instituted in the local courts, and one involving many intricate questions of mining law.

LARIMER COUNTY.

At Fort Collins, a meeting of citizens was recently held to take the necessary steps to organize a stock company to bore for oil, coal, and gas. It was decided to file articles of incorporation, and to solicit the citizens to subscribe to the stock

OURAY COUNTY.

Owing to the announcement made on the 15th of October by the mine-owners, that miners' wages would be cut fifty cents per day on November 1st, the miners at Telluride have quit work, and every shipping mine in Marshall Basin is closed. Both the mine-owners and men are determined to stand firm.

Digitized by Google

SAN JUAN COUNTY.

BISMUTH.—The concentrator of this company was started up, and all the ore at the mill run through with success. The 3500-foot tramway will be completed soon, and will be ready for business during the winter. About 60 men are employed about the mines and mills, and at present matters are rapidly arranging at the Sampson mine to allow them an opportunity to make a production equal to the capacity of the mill, which will be run night and day with the capacity of 30 tons every twelve hours.

ECLIPSE.—The capacity of the mill is to be enlarged. Arrangements are to be made for working the Red Cross and Mountain Queen mines, owned by the company. The smelter will be put in operation to work these ores.

LITTLE ABBIE.—The president of the company has arrived in Silverton for the purpose of straightening up the affairs of the company and resuming work on the Abbie tunnel, and opening up the Belcher vein on Picayune Mountain. This property was worked last winter by a large force of men, who quit work on account of the company's failing to pay them monthly. The company owns a large group of mines, extending up over Picayune Mountain to Eureka Mountain.

SUMMIT COUNTY.

HORN-SILVER.—This group of claims at Red Cliff, numbering eight, has been sold for $35,000. The property was purchased by a syndicate. Work will begin at once.

KINGFISHER.—The new strike made in No. 2 drift consists of two and a half feet of fine ore.

DAKOTA.

FATHER DE SMET.—The report of the superintendent for the week ended November 1st shows: Ore extracted from the first, second, and third levels, 2895 tons. Ore milled, 3000 tons. Golden Gate east cross-cut, third level, advanced 9 feet; total length, 105 feet. Golden Gate south header, second level, advanced 6 feet. Header in 77 feet.

HARNEY PEAK TIN MINING COMPANY.—This company has recently been organized at Rapid City. The property consists of twenty tin-bearing quartz locations near the summit of Harney's Peak, and a large scope of stream-tin ground lying along the branches of Palmer's Gulch, together with various water-rights, mill-sites, etc. Mr. G. F. Randall, an English engineer and representative of English capitalists, has reported favorably on the property, and before his departure made the following proposition to the company: He to organize an English company with a capital of $500,000; such company to furnish $250,000 for developing the mines and purchasing machinery within a certain specified time; the local company to turn over the property upon receipt of $250,000 or one half the capital stock (non-assessable). An agreement which binds the company to give a bond upon the property on payment of $10,000 has been executed, and as soon as part of the money has been paid, work will be commenced. Unless the Black Hills *Journal* has horribly garbled the "Professor's" report, it furnishes ample testimony for the conclusion that he does not know what he is writing about, not to speak of how he writes. For the edification of our readers, we quote:

The first tin ore is found about half a mile from the base of the mountain, at which point a ridge of greisen quartz rock some 300 feet in width and from 100 to 500 feet in hight, above the surface, is found. This ridge extends for over one mile, and capes the two branches of Palmer Creek, producing suitable sites for mills, and adequate water-power for concentrating-works. The rock is composed of mica, silica, and porphyry, carrying a large percentage of black tin crystals, which yield under assay from 50 to 75 per cent of pure metallic tin and from 8 to 10 per cent of nickel. Large veins are found in this ridge which will yield 75 per cent of black tin crystals, and vary in width from three to eight inches. No rock could be easier or better situated for mining purposes. I was able with an ordinary hammer to break it at any point; and in some hundreds of samples which I examined, was unable to discover any except what contained a high percentage of tin crystals. At a distance of a quarter of a mile, running parallel with this, the erect ridge is continued. This is of still larger dimensions, and extends from the head of the east branch of Palmer's Gulch to nearly the summit of the mountain, and in some cases 600 to 800 feet in hight ABOVE THE SURFACE. The tin crystals in this mass are almost incredible, in many cases where they occur being 50 per cent of the quartz-rock—the black crystals in contrast to the white spar and shining mica, presenting a most beautiful appearance, exceeding in size two and a half inches in diameter, yielding under analysis from 70 to 75 per cent pure tin, and from 8 to 15 per cent of nickel. From this to the top of the mountain, a distance of about 1000 feet perpendicularly, the same formation extends, containing ore in perfectly inexhaustible quantities. This rock needs no mining whatever. It is simply throwing down the greisen rock into chutes and ore-bins and carrying the same to the mill for crushing and concentrating. To form any estimate of the extent of this formation is impossible, the magnitude is so great, and it is no exaggeration to state that it requires a fortnight even to survey this mass of rock. These mines will certainly rule the tin markets of the world. The ore can without doubt be mined and concentrated for from five to ten per cent per ton, with suitable appliances, and the quantity is so enormous that for years to come none but the richest portions need be touched.

The mining community of the Black Hills should raise a subscription to pay the expenses of the "Professor's" trip back to England on condition that he will never come back. He is hurting the prospects of their country as a future tin-producing district. Turn him out!

GEORGIA.

LOUD.—The sale of this placer mine will take place January 8th, at Cleveland, O.

IDAHO.

The scarcity of cars at Hailey to move the Wood River ores and bullion is getting alarming and is seriously interfering with the yield of the mines.

ALLEN.—This group of mines has been purchased by the Buzzo Silver Mining Company for $50,000.

MAINE.

A stock company has been formed to work the iron mine at Webb's Mills, Casco, discovered many years ago. The necessary buildings are in course of construction. The ore will be shipped to Portland.

DOUGLAS.—The annual meeting was held at Bangor recently. Frank H. Williams was chosen secretary, and the following board of directors was elected for the ensuing year: Eugene H. Clapp, Horace P. Tobey, and Frank H. Williams, of Boston; Frederick M. Laughton and John S. Jennes, of Bangor; Hanson Gregory, Jr., of Rockland; and William D. Swazey, of Rucksport. No business of public importance was transacted. The result of the subsequent directors' meeting, held in Boston, has not yet been learned.

MICHIGAN.

The following mines mentioned below produced during October as follows:

	Tons.	Lbs.
Franklin	195	1355
Huron (about)	70	....
Pewabic	48	450

It will be seen that the Franklin comes to the fore with the largest product ever taken from the mine in one month. The Huron also makes a good return, considering that the stamping capacity of the mine is confined to one head.

English capitalists have lately visited Rockland for the purpose of examining and buying the National, Minnesota, Rockland, and Superior copper mines. The different properties adjoin and have a length of 3½ miles, and aggregate about 7000 acres. If they buy this, they propose to consolidate all the properties and make one or possibly two mines, and drive in an adit east from Ontonagon River at a depth of about 500 feet, and this will unwater all of the old mines and save future pumping.

ARGYLE.—This iron mine has been closed down, owing to the depressed condition of the market.

ERIE.—The sale of this iron mine, negotiations for which have been pending for some weeks, is announced. The purchasers of the property, of whom Judge Hoadley is said to be one, have not yet organized as a company. The purchasers intend to buy other properties on the same range.

INDIANA IRON COMPANY.—At a special meeting recently held, the capital stock was increased. The amount is not reported.

METROPOLITAN.—A new and hitherto unknown vein of blue ore, 16 feet wide, is reported as the latest development.

STERLING.—Work has been entirely suspended.

WHITE PINE.—This copper mine, on Section 5, two miles east of Nonesuch, and on the same vein, and down 135 feet, with good show of copper from the surface down to the bottom, has just stopped work for the winter, on account of the low price of copper, but will start up next spring with stamping machinery.

NEVADA.

ELKO COUNTY.

NAVAJO.—The new pumps have been tested, and work satisfactorily. Hoisting ore has begun. It is though tthat there is sufficient water to start the mill soon after the first of November.

EUREKA COUNTY.

SILVER CONNOR.—The body of ore found on the 250-foot level is developing. The ore runs in value at the rate of $60 per ton.

SILVER STATE.—The mines comprising the company's property are the original Baltic, Hilma, Confidence, and Silver State, all of which are United States patented claims. The company has run a tunnel under the apex of the property, where it expects to strike the vein at a depth of from 200 to 300 feet. The main tunnel is 370 feet in length. At the distance of 320 feet from the mouth of the tunnel, a favorable iron formation was struck and followed by a cross-cut run in a northerly direction, which is now in eighty-one feet. Forty feet from this cross-cut, cross-cut No. 2 begins. It has a present length of a little over 100 feet. The face is in quartz and iron, with low-grade ore, which is followed in the working of the present contract.

STOREY COUNTY—COMSTOCK LODE.

The station for the new hydraulic pump for the combination shaft is completed, and they are now leveling down the rock for the timbers on which the machinery will be set up. November 3d, the time expired in which the machinery had to be completed by the contractors at San Francisco.

ALTA.—The water is below the top of the 2150 drift, and is steadily lowering. This is the last level remaining to be drained; but as the source of the water is on this level, progress for the last 20 feet has been necessarily slow. It will take some time to put cages in and perform other necessary repairs before resuming prospecting.

NORTH GOULD & CURRY.—The lawsuit which has been pending for so long a time against this company has been settled and the case dismissed.

WHITE PINE COUNTY.

MARTIN WHITE.—At the present time, work is carried on in the mine, taking out ore and prospecting for more. There is no ore reduced, but it is accumulating.

NEW MEXICO.

BERNALILLO COUNTY.

The five placer mining companies recently formed in Albuquerque for working the placer grounds at Golden have been consolidated.

GRANT COUNTY.

There are eight claims in the vicinity of Kingston, in which ore has been struck. These claims are the Bullion, Superior, Lady Franklin, Iron King, Brush Heap, Andy Johnson, Illinois, and Monasca. The latter is on the South Percha, but three miles distant from the town. In addition to these, the claims which promise well in both low and high-grade ores are numerous.

OLD MAN.—Every thing looks promising. As stated, there are fully 2000 tons of ore out. This is mainly low-grade or milling ore, the body having been stripped of high-grade, which has been shipped and sold. In the mine, enough ore is in sight to keep the mill running all winter.

PENNSYLVANIA.

The Silver mine in Garland, which caused considerable agitation two years ago, is again worked. A company of capitalists sank a shaft at that time, but abandoned it when thirty feet deep. The owner of the land and another man are now working it. The latter is to sink a shaft 100 feet for half of the profits. No person is allowed to enter the shaft, and the operators refuse to speak on the subject.

UTAH.

BEAVER COUNTY.

CACTUS.—The company has just put a new Knowles pump into the mine. The new concentrating jiggers have arrived in Frisco, and will soon be erected and in operation. A series of tanks and reservoirs has been built, of sufficient capacity to hold all the water that passes through the machinery, so that it may be pumped back, and used over and over again.

BOX ELDER COUNTY.

LEAD.—The mine is producing about fifty tons of jigging ore daily, and is reported to be looking well in all its workings.

MARTIN TELEGRAPH.—This location, situated near the Yosemite, is working about one hundred men, and is sending to the surface large quantities of good ore.

JUAB COUNTY.

MAMMOTH.—Reports in Salt Lake papers state that this company has offered to compromise with its creditors, paying twenty-five cents on the dollar.

SUMMIT COUNTY.

BON HOMME.—An incline is sinking which is now about seventy-five feet deep, all the way in a vein from four to seven feet thick. The vein carries a large amount of black manganese.

UINTAH.—Preparations are making by this company to resume work on its claims at the base of Rebellion Hill.

WYOMING.

CARBON COUNTY.

Considerable work has been done at Ferris during the past months on the Pride of the West, Columbia, Leonidas, and some others, all of which show mineral in paying quantities, the character of ore being argentiferous galena, carbonates, and chlorides. Many locations have recently been made.

COLUMBIA.—The mine has a vein four and a half feet in width, carrying galena, carbonates, and gray copper.

LEONIDAS.—This is a contact vein ten feet in width, the ore being galena, oxides, and carbonates.

PRIDE OF THE WEST.—Two shafts were sunk, one tunnel driven, and an open cut made during the summer. All the developments made show favorable prospects.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Nov. 9.

Business in the mining market continues very dull, and a holiday coming in this week has tended to further demoralize the market. The principal feature of the market was Horn-Silver, which suffered a further decline from last week's prices. Chrysolite was an exception to the general depression which seemed to prevail, and was quite strong to-day. A full summary will be found below. The total number of shares sold aggregates 97,665, as against 117,935 last week.

The Comstock shares were very quiet at about steady prices. California sold from 26@25c. under a small business. Consolidated Virginia was moderately dealt in at about steady prices, selling from 48@45c. Sierra Nevada was weak, with a very small business, selling from $3.80@$3.60. Hale and Norcross sold at $2.10. Sutro Tunnel was quiet and steady, selling from 16@15c.

The Leadville stocks were moderately dealt in and were steady. Amie was quiet and steady at 12@11c. Chrysolite was strong, under a small business, selling from $1.15@$1.30. Iron Silver was moderately dealt in at irregular prices; it sold from $3@$2.90. Leadville was quiet and steady at 45@48c. Little Chief was strong last Saturday at 60c., but sold through the week at 57@55c.; the stock was fairly dealt in. Little Pittsburg was strong, under a small business, selling from 50@60c. Climax sold at 6c.

The Bodie stocks were very quiet. Standard was steady, selling from $6.25@$6. Bulwer was steady, selling at 50c. Bodie sold to-day from 45@40c.

The Tuscarora stocks were quiet and steady. Grand Prize sold at 45@40c., with a small business. Belle Isle was quiet and steady at 43@40c. Navajo was strong, under a small business, selling from $4@$4 10. North Belle Isle sold at 65c. Elko Consolidated was quiet and steady, selling from 18@19c., assessment paid. Argenta sold at 22c.

In the miscellaneous list, Alice was moderately dealt in and was weak, selling from $2.80@$2.50. Bassick was quiet and steady, selling from $8.50@$9. Father de Smet sold at $3.50. Horn-Silver was fairly dealt in at weak prices; it sold from $6@$5@$5.25 dividend unpaid, and from $4.60@$4.90 dividend paid. Robinson Consolidated was quiet and irregular, selling from 48@43@46c. Sierra Grande sold from $1@96c. under a very small business. Castle Creek was strong, with moderate transactions, selling from $1.05@$1.20.

Barcelona was weak, under a small business, selling from 27@24c. Bradshaw was quiet at 22@21c. Caledonia was quiet and steady at 25@27c. Decatur was quite active at 4c. Eastern Oregon was active and steady, selling from 43@47c. Harlem was fairly dealt in at irregular prices; it sold from 94@98@96c. Hortense was quiet and steady at 10@11c. Lacrosse sold at 9c. and Rappahannock at 8c. Red Elephant sold from 6@5c. with small transactions. Sonora Consolidated was quiet and a little weak, selling from 28@25c.

At a meeting of the stockholders of the Chrysolite Silver Mining Company, held on Wednesday last at the office, No. 18 Wall street, this city, the following trustees were elected for the ensuing year: R. W. Raymond, H. A. V. Post, W. S. Gurnee, D. S. Appleton, Abram S. Hewitt, E. F. Bedell, J. F. Tams, C. S. Knowles, William Borden, Nicholas Rath, and R. H. Thurston.

A large array of counsel appeared last Monday before Judge Wallace, of the United States Circuit Court, and Judge Brown, of the United States District Court, who held court jointly, to argue motions for the removal of five suits against mining companies from the Federal to the State courts. The first case was that of Henry T. Cutter *against* Daniel S. Appleton, Charles A. Whittier, and others, and the Chryso lite Silver Mining Company; the second was that of Sylvester H. Langdon, Francis A. Fogg, Clinton B. Fisk, John S. Williams, James Clyne, Morris Seligman, and the Silver Era Mining Company; the third was that of Philip D. Jenkins *against* Charles Dennis, Hiram Dewing, Walter T. Hatch, and the Dunderberg Mining Company; the fourth was that of Eliphalet Nott and other stockholders *against* Henry Clews, John B. Alley, and others, and the Los Nueve Minas de Santa Maria Gold and Silver Mining Company; and the fifth was the case of George W. Boyd and other stockholders *against* Andrew W. Gill, Stephen B. Elkins, Augustus Ebert, Preston B. Plumb, William W. Macfarland, and the Amie Consolidated Mining Company. Decision was reserved in all cases.

MEETINGS.

The Animas Silver Mining Company, No. 35 Broadway, New York City. Annual meeting of stockholders and election of trustees, November 27th, at twelve o'clock M.

The Camuchin Consolidated Silver Mining Company, No. 35 Broadway, New York City. Annual meeting of stockholders and election of trustees, November 27th, at twelve o'clock M.

The Descubridora Consolidated Silver Mining Company, No. 35 Broadway, New York City. Annual meeting of stockholders and election of trustees, November 27th, at twelve o'clock M.

The South Yuba Water and Mining Company, No. 23 Nassau street, New York City. Annual meeting of stockholders and election of trustees, November 28th, at twelve o'clock M.

The Valenzuela Consolidated Silver Mining Company, 35 Broadway, New York City. Annual meeting of stockholders and election of trustees, November 27th, at twelve o'clock M.

DIVIDENDS.

The Plymouth Consolidated, of California, has declared its sixth dividend, amounting to $50,000; total dividends, $300,000.

DIVIDENDS PAID BY MINING COMPANIES DURING THE MONTH OF OCTOBER, AND FROM JANUARY 1ST, 1883.

PIPE LINE CERTIFICATES.

The petroleum market up to to-day was absolutely featureless, the fluctuations being within a narrow range and the dealings of a limited character. To-day, however, a reaction set in, and the market was quite active at strong prices, closing at the highest figure for the day. There was no news from the oil-fields to affect the market either way, and the dealings were simply confined to the local traders.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Nov. 3	$1.09¼	$1.10⅜	$1.09⅛	$1.10⅜	2,990,000
5	1.10⅜	1.10⅞	1.09⅞	1.09⅞	2,839,000
6					
7	1.09¾	1.10¼	1.09¾	1.09⅞	1,779,000
8	1.10¼	1.10⅜	1.10	1.10	1,310,000
9	1.10⅛	1.12⅛	1.09⅞	1.12⅛	3,727,000
Total sales					12,645,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, November 8.

There is no feature to report in regard to mining stocks for the past week. The market is dull and uninteresting, with very little doing and no incentive to speculation. Ingot copper holds quite steady at 15@15¼c., and the market for producing mines, while quite limited, is nevertheless firm, and small lots for investment purposes are taken at current rates. Calumet & Hecla sold at $240, and is in firm demand at that price. Franklin declined from $11⅝@$11 for a small lot, with later sales at $11½@$11¼ for regular stock, and $11¾ buyer 60. Quincy is unusually quiet; sales of 20 shares only reported for the week at $50; but $51 was bid for it to-day, without bringing out the stock. Pewabic advanced from $2½ (October 27th) to $3¼, at which price a small lot was sold to-day, and more is wanted at the same price. Osceola is very firm at $18½, with but little stock offered. A sale of 100 shares Allouez is reported at $1½, the last sale being September 26th, at the same price. The rest of the list is without any reported transactions.

The silver stocks continue dull, and, with the exception of Sullivan, almost without feature. Bonanza sold at $1½, same as before. Catalpa, dull at 27½c. Harshaw sold at 50c. Sullivan has been the most active stock on the list, and declined from 96@81¼c., with a subsequent rally later to 95c. The delinquent stock was sold at $1, 1900 shares being sold to pay the assessment of 25c. per share on 7600 shares defaulted. Bowman Silver declined to 10c.; this, for a stock on which assessments of 15c. per share have been paid within a year, offers but poor encouragement to stockholders. Empire declined to 25c. Massachusetts & New Mexico offered at 3c Dunkin, 23@26c.

Digitized by Google

3 P.M.—At the afternoon Boards, Catalpa sold at 27½@29c. Franklin, $11½. Closing prices: Atlantic, $10 bid, $11 asked. Bonanza, $1 7/16@$1¾. Calumet & Hecla, $240 asked. Huron, $1¼@$1¾. Osceola, $18@$18½. Pewabic, $3. Quincy, $51@$51¾. Silver Islet, $3½@$4. Sullivan, 92½@95c.

BULLION MARKET.

NEW YORK, Friday Evening, Nov. 9.

Under a fall in the price of exchange on India, the silver market in London has receded somewhat, and affected the price here, as shown by the figures of the accompanying table:

DATE.	London. Pence.	N. Y Cents.	DATE.	London. Pence.	N. Y Cents.
Nov. 3	50 15-16	110½	Nov. 7	50 13-16	110¼
5	50 15-16	110½	8	50 13-16	110¼
6	50⅞	Holiday.	9	50 13-16	110⅜

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

MINES.	States.	Month of September.	Year from Jan. 1st, 1883.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended November 9th, as compiled from various sources, amounted to $335,896, as against $247,000 reported for the previous week. The receipts from January 1st, 1883, to date are $9,898,443.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended November 3d	$356,860
Corresponding week last year	117,844
Since January 1st, 1883	12,685,819
Corresponding period last year	44,561,721

Imports.

Week ended November 3d	$1,526,520
Corresponding week last year	447,712
Since January 1st, 1883	15,668,367
Corresponding period last year	4,728,631

Foreign Bank Statements.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at three per cent. During the week, the bank lost £15,000 bullion, but the proportion of its reserve to liabilities was raised from 43⅛ to 43⅝ per cent, against 37¼ per cent a year ago. The weekly statement of the Bank of France shows losses of 260,000 francs gold, and 2,144,000 francs silver.

Coinage at the Philadelphia Mint.—The coinage executed at the Mint in October aggregated 9,497,800 pieces, valued at $1,359,914.50. This amount was made up of 1,050,050 silver dollars, 50 half-dollars, 50 quarters, 1,410,050 dimes, 2,461,000 five-cent pieces, 300 three-cent pieces, and 4,576,300 one-cent pieces.

United States Assay-Office at New York.—Statement of business for the month ended October 31st, 1883:

Deposits of gold:		
Foreign coin	$1,361,000	
Foreign bullion	858,000	
United States bullion	470,000	
United States bullion (re-deposits)	305,000	
Jewelers' bars	98,000	
Refined gold	347,000	$3,439,000
Deposits of silver:		
Jewelers' bars	17,000	
Foreign coin	7,700	
Foreign bullion	33,000	
United States bullion (contained in gold)	11,500	
United States bullion (re-deposits)	4,200	
Bullion, Arizona	2,200	
Colorado	29,500	
Dakota	27,100	
Idaho	14,400	
Lake Superior	1,400	
Montana	130,700	
Nevada	1,700	
New Mexico	19,600	
Utah	86,600	
Refined silver	82,400	469,000
Total deposits		$3,908,000
Gold bars stamped	$1,977,091	
Silver "	518,378	2,495,469

METALS.

NEW YORK, Friday Evening, Nov. 9.

Copper.—It is reported now that the extension of the Lake contracts alluded to some time ago as carrying the deliveries up to the close of the year, are really brought down to the beginning of April, the amount involved being reported to be twenty millions of pounds. There is an elasticity about such engagements which does not inspire much confidence. There is one feature in connection with the deliveries which to some extent checks a movement which has had much significance during past two years. Much of the copper is delivered at Waterbury and other centers of the manufacturing trade. This, to some extent, hampers the exchange of other brands of copper for Lake.

During the week, Lake copper has sold at 14⅞c., though probably the quantity available at that price is very small. Larger blocks of Baltimore, aggregating 500,000 pounds, have been placed. We quote 14⅛@14⅝c., according to brand.

The advices from abroad are not encouraging, and, in spite of all that is said to the contrary, it is difficult to see how, as we have already contended, our own market can resist the influence. London cables to-day £60 15s. cash and £61 f. o. b. for Chili Bars, and £66@£67 for Best Selected.

Tin.—The market is dull and weak, under the pressure of late and prospective arrivals. There are now 400 tons on the dock, and 275 tons are due on Sunday. We quote 20c. for Straits, large lines, cash. England cables £90 to-day.

Lead.—Since our last, the market has been dull, sales not aggregating more than a few hundred tons at 4c. for Common and Refined. Lead could be bought at 3·95c. for Common, if any body could be got to make an offer at that figure. Buyers, however, are frightened rather than encouraged at every further concession. While on the whole, the situation, as we have repeatedly stated, warrants the low figure of 4c., it can not be denied that at the present moment there appears to be some special effort to depress prices below it. It looks as though somebody were at work trying to bring smelters to the conviction that they must accept lower figures. The manufacturing trade will be busy for the next four or six weeks, and for that time some support from that quarter may be looked to. How matters will shape after that period remains to be seen. Until then, we do not believe that the situation warrants any sustained downward movement.

Messrs. John Wahl & Co., of St. Louis, wire to us as follows to-day:

Our market has declined slowly since our last report, on sales of 250 tons of Refined at 3·75c. There is very little doing, the demand being only moderate, with quotations nominally 3.70c.

Messrs. Everett & Post, of Chicago, telegraph us to-day:

The market is flat and weak, sales not aggregating more than 700 tons at 3·75c. down to 3·70c., closing nominally at the latter figure.

Soft Spanish is cabled from London £11 12s. 6d.

Spelter.—This metal has not shown any symptoms of the improvement so confidently expected months ago. It is quiet at 4⅝@4½c. for Ordinary Domestic. London cables £15 17s. 6d.

Antimony.—This metal is slightly stronger.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Nov. 9.

Mr. Edward J. Shriver, Secretary of the Metal Exchange, has the following returns:

One hundred and thirteen furnaces, all kinds—sixty-four in blast, forty-nine out of blast.

All grades.	Stocks. Oct. 1.	Stocks. Nov. 1.	Production. In Sept.	Production. In Oct.
Anthracite	23,979	22,550	11,880	13,557
Bituminous	30,235	28,888	19,967	23,020
Charcoal	20,635	20,606	7,396	8,124
Grand total	74,849	72,044	39,243	44,701

American Pig.—Inquiries are getting more numerous, and the conviction is gaining ground generally that, if we have not come down to "bed-rock" in all departments, we are very near the lowest prices. Consumers, on the other hand, do not show the slightest anxiety, and have no cause for it. During the week, sales have been fair at prices practically unchanged. Foundry iron remains $20@$22 for No. 1 and $19@$20 for No. 2, with Gray Forge at $17.50 @$18.50 at tide-water. Bessemer pig is dull, and with the lower prices for rails, will not find buyers except at very close figures. We quote $20@$20.25. Spiegeleisen is quiet at $30 for 20 per cent.

At the Exchange, the following sales were recorded: To-day, 1,000 tons No. 1, March, at $20.50.

Scotch Pig.—There is very little to report, the situation remaining unchanged, with a light business and moderate supplies.

We quote ex ship and to arrive: Coltness, $23; Langloan, $23@$23.25; Summerlee, $22.50@$23; Eglinton, $20.50@$21; Glengarnock, $21.75@$22; Dalmellington, $20.75@$21.

At the Exchange, the following lower cable quotations were received to-day: Coltness, 55s. 6d.; Langloan, 54s. 6d.; Summerlee, 54s.; Gartsherrie, 53s.; Glengarnock, at Ardrossan, 48s.; and Eglinton, at Ardrossan, 46s. 9d. Warrants at the Exchange to-day were 44s. 1d.

Rails.—The wide publicity given to the open drop in the price of rails had brought out many inquiries and negotiations are now pending for the closing of several large contracts, and it is likely that in the next fortnight considerable orders will be placed, all of course for next year's delivery. Buyers generally appear to recognize the fact that the low prices are causing competition to narrow down, and it is believed that they will soon abandon all efforts to obtain further concessions.

Old Rails.—The market has shown little animation. We quote $21@$22 for Tees.

Scrap.—We quote $23 ex ship.

Philadelphia. November 9.

The views of leading iron men as to the future of the market are but little more hopeful than two or three weeks ago. Rumors are afloat as to further concessions and shading of prices from figures which have heretofore been considered bottom prices. This has had an unsettling effect upon those who were about ready to order stocks for the rest of the year; and it has also arrested the tendency to speculate in standard irons which was developed a few days ago by offers for large lots. At present writing, the outlook is unfavorable to any improvement, either in demand or prices. Foundry irons are selling very slowly. Prices for ordinary are as low as $20, while $20.50@$21 is quoted and paid for some of the better brands, with some small sales at $21.50. No. 2 has sold as low as $18.50, and the highest heard of this week was $19.50. About $19 represents the average, at which only small lots have sold. The leading makers consider the situation encouraging, but have no business or inquiries to justify their opinion. Millmen are looking up large lots of Forge, and White and Mottled have sold at $16.50@$17 delivered. Straight Forge, $17.50@$18.50. Most of the business is in from 50 to 100-ton lots, with a few contracts for larger lots for delivery this and next month. The improvement expected will be delayed still longer. Too many offerings are on the market for firm prices, and more stock is at furnace-banks than can be readily moved, and sellers are more urgent than buyers. Some of the stronger companies are putting a good face upon the market, and report active business probable for the future; but it must be admitted that the trade is without evidences of activity, beyond that necessitated by current requirements.

Foreign Irons.—Several offers for Bessemer and spiegeleisen have been withdrawn. For Bessemer, $20.50 is asked, and $30.50 for Spiegeleisen.

Muck Bars.—A further weakness of 50 cents is to be reported; sales have been made at $33, though some makes are held at $33.50.

Blooms.—Sales of Blooms have been made as low as $55 and $45, but some makes are higher.

Manufactured Iron.—Prices are weak, and sales have been made at 1·80c. for what passes as Refined. Very low prices are taken, in competition with Western mills. Eastern dealers prefer to pay ⅛c. more for home iron, especially small buyers. Very little iron sells above 2c. Manufacturers are loath to admit that prices are declining and demand likely to continue as it is, but the indications all point that way. Two or three have received fair orders this week, but reports, especially from the country mills, are unfavorable, and show a positively declining tendency.

Plate and Tank Iron.—Mills on Plate and Tank iron are doing fairly, and taking orders for the first quarter of next year in some cases at 2·40@2·50c. for Common Plate and 3¾c. for Shell in small lots. Inquiries for flange and fire-box have come to hand this week. Locomotive requirements are active and steady. The ship-yards are consuming sufficient to impart a fair activity to the trade.

Structural Iron.—Two or three large specifications have arrived, and reports from the bridge-works continue as favorable as heretofore. Definite information can not be given at present as to the probable transactions for this and next month, but there is a good deal of work yet to be done. Angles, 2·40@2·50c., Tees, 2·75@3c. Beams and Channels, 3·40@3·50c. These figures have been shaded in reply to this week's inquiries.

Wrought Pipes and Tubes.—Mills on pipes and tubes are busy, and negotiations are about closing for large lots of pipe iron.

Steel.—An improving demand for low-grade steels is reported, in consequence of heavy shadings offered.

Steel Rails.—The action of the Scranton people has prevented the closing of some negotiations which were in hand a week ago. Small lots have been ordered at $37, but no large transactions are likely to take place at present, although it is dangerous to accept statements as to future intentions. Manufacturers will probably find it necessary to meet the drop half way. Several large lots are in negotiation.

Old Rails.—$23.50 is asked for Foreign and American Tees. Bridge rails nominal. Double-Heads, $25.50

Scrap.—$24.50@$25 is quoted for No. 1 and $18.50 @$22 for No. 2. Cargo, $23, nominal.

Pittsburg. November 7.

Pig-iron is in moderate demand at prices lower than have been reported for a long time. Buyers are still refusing to anticipate requirements, hoping and believing that lower prices will be reached; but furnace men say that they will be compelled to blow out if any further decline takes place, prices now being almost, and in a few cases quite, down to cost of production. C. B. Charcoal has sold at $30, and Warm Blast at $28. Red Short, $20 cash; standard brands of Neutral Forge, $17.50@$18. Muck Bars are dull and have declined to $32.50. For manufactured iron, 1·80@1·90c. is quoted. The market is weak and the demand dull except for small lots for immediate use. It is still uncertain whether the Nail Association will order a suspension, or agree to continue production. Stocks of nails are not large, but the demand is dull and prices weak, and it is thought that a suspension of the 2500 nail-machines will soon give the market a better tone. Mills on wrought iron pipe are fully employed, and the demand is active, although there is a great deal of complaint as to prices. Discounts on gas and steam-pipe, from 73 to 75 per cent off; boiler tubes, 60 per cent off. Old Rails are selling at $24.50. Steel Rails, $37.50@$38 for fall and $36 for next year's delivery, with moderate sales reported. Merchant steel is without improvement, and prices continue low. Quotations for railroad track supplies are unchanged, and the demand is moderate. Scrap, $21@$23 for No. 1.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Nov. 9.

Anthracite.

If any thing, the situation in our local market has grown worse, and there is almost a complete stagnation. Buyers, who had been assured months ago when they were stocking up heavily that their interests would be taken care of, are disgusted with the turn of affairs, and enter the market only when absolute necessity compels them to. The great majority of them by far prefer to deliver from accumulated stocks, letting them run down slightly, than keep their supplies up as is usual at this season. In spite of the fact that the West is taking more coal, that the Southern markets have absorbed more anthracite than usual, there is an excess of coal here, and the attitude of buyers makes the situation all the worse. Concessions are the rule, and yet it is difficult to place coal. Besides, the falling off in prices demoralizes that part of the trade, a heavy part of it, which consists in deliveries on contracts.

There is absolutely no hope that there will be a restriction of output this month; not because the state of the trade does not demand it, but for another reason. The beginning of December, however, will have to witness a stoppage, not alone of half time, but for at least a week. Prices are lower, $4.15@$4.20 for stove coal.

Bituminous.

The Philadelphia correspondent of *Coal* says: The total production sent to Eastern markets for the year is 4,088,196 tons—an increase of 510,272 tons over the production for last year. The figures for last week are 107,782 tons. The Clearfield output was 57,455 tons; Broad Top, 13,048 tons. The smaller operators still complain of the lack of cars, but some of them have recently received more than during September. There is a disposition shown to meet trade requirements as far as possible, but the necessities of some shippers would lead them to precipitate more coal on the market than is needed, could they be as liberally supplied with cars as they desire. The company is endeavoring to serve the interests of both producers and consumers to a certain extent, and at the same time to profit by the heavy traffic. The shipments from the Cumberland region for the week are 57,043 tons, and for the year, 2,086,936 tons, or double those of last year.

Buffalo.

The bituminous coal trade of Port Arthur, L. S., has already reached a considerable magnitude. Last year, 5000 tons were received at that port (the only port of entry in Manitoba), and this year the aggregate may exceed 90,000 tons, including 12,000 tons of anthracite, which is quoted at $13@$14 per ton at retail. From the want of proper shipping facilities in the way of handling soft coal at this point, the bulk of the movement has been from upper Lake Ports. Railroad freights also ruled too high from the mines to Buffalo. The cost of handling soft coal in Buffalo from cars to vessels by wheelbarrows is about thirty cents per ton; at Cleveland and Sandusky, where they have derricks, only from ten to twelve cents. The firm here which has contracts with the Canada Pacific Railroad expects to send 200,000 tons to Port Arthur next year and to use its own coal instead of purchasing from the producers. The firm will erect derricks and all conveniences at this port if possible before the opening of next season's business.

Chicago.

Reports of new discoveries of soft coal in the territory tributary to Chicago are constantly coming in, and it would seem as if the whole Western country were underlain by some kind of coal, better or worse in quality. Portage County, Wisconsin, is happy over the discovery of a vein of coal of fair quality, while a rich vein of excellent quality has been found the past week at Manning, Carroll County, Iowa. A company with $200,000 capital has been formed to work the newly discovered mines at Victoria, five miles north of Bismarck, on the Northern Pacific road. A Canadian geologist who has just returned from a tour over the Canadian Pacific Railroad, reports that he has found indications of abundant coal—on the plains lignite, on the foot-hills bituminous, and in the mountains anthracite of fair quality. There are reports of other discoveries, too numerous for mention, constantly coming in, many of which of course amount to nothing.

Cleveland.

The latest from the "new find" seems to establish my statement of two weeks ago. From samples of the drillings sent to Professor Orton, he declares it to be bituminous shale or albertite, containing about 50 per cent of fixed carbon. From the reputation of the men and the witnesses present at the drilling, I am satisfied it is an honest find, so far as they are concerned, and therefore not "salted," as some have charged; but as to the quantity or value of the "find," the presumption is against its being of any considerable dimensions, and its positive value can only be learned by sinking additional holes by a more systematic method, which will probably be done, as the quantity is evidently greater than any heretofore struck in this region.

Horsford's Acid Phosphate,

Unequaled.

DR. R. M. ALEXANDER, Fannettsburgh, Pa., says: "I think Horsford's Acid Phosphate is not equaled in any other preparation of phosphorus."

ROTHWELL'S

Great Map of the Wyoming Valley.

This, the most elaborate and accurate topographical map ever made in this country, outside of the Coast Survey, covers an area of TWO HUNDRED SQUARE MILES, and the work upon it cost over $12,000. It represents a coal-field which produced in 1882 over 13,000,000 tons of Anthracite. The Map was constructed altogether from original surveys. Every Road, Colliery, Building, or land or property line existing at the time is accurately located. The surface configuration is shown by CONTOUR LINES TEN FEET APART, VERTICALLY; and the elevation of every point above sea-level is given

But a small edition of this Map was printed, and the plates were then destroyed.

A few copies are for sale

Price: On thick heavy paper $25

On bond paper, for mounting 25

The six sheets can be mounted separately, or in a single roll 15 feet long by 42 inches wide.

FROM England, comes the news that the office of Keeper of Mining Records, so long and ably filled by Mr. ROBERT HUNT, has been abolished, and that the work of collecting the mineral statistics of Great Britain will now be performed by the mine inspectors under the surveillance of the Home Office.

DISPATCHES from Washington to the New York daily papers unfriendly to the administration represent naval circles in that capital to be considerably excited over a criticism, published in the *Engineer*, of the design of engine and boilers of the new steel cruiser Chicago. It may be well to warn Americans, before they attach too much importance to what the *Engineer* says, to state that the pages of that journal have for years maintained an attitude of hostility to every thing that is American.

ROPE tramways for transporting coal, ore, stone, etc., particularly over very difficult ground that would involve complex road construction, are much older than is generally believed. Recently, a description, with drawings, was found in the archives of the city of Dantzic, Germany, showing the arrangement designed in 1644 by a Dutch engineer, ADAM WYBE, to carry earth excavated on one side of the city fortification ditch across it to the other side. It was only when wire rope became known and generally appreciated that such tramways again came into use and assumed the importance they now command.

THE low prices of copper during the current year have played sad havoc with a large number of Western enterprises, and there are few of the smaller producers figuring in last year's reports of production that have been able to stand the strain. In Arizona, six have succumbed; in Wyoming, Montana, and Nevada, one; and in New Mexico, there is not now, so far as we know, a single concern running. The East has dwindled down to insignificant proportions, and even some of the largest mines of Arizona have shown symptoms of a decline, or are erratic to an extent that does not speak well for their future. Among those which have temporarily suspended operations, is the Arizona Copper Company, of the Clifton District, though its idleness is due to extensive preparations for a future large output. At a recent meeting of the company at Edinburgh, some facts were brought forward which are of interest. The company has nearly completed its road, 70 miles in length, and is trying to provide for the expenditure incurred, £290,000, in calling for a loan of £300,000, the purchase price of the mines having been £600,000. A new plant has been contracted for, as already noticed, because, as the chairman stated, the old smelters were costing them as much as $150 per day for running expenses. They hope to reduce the figure to $200 for four furnaces. It is estimated that the cost of mining and smelting 15 per cent ore will be $19 per ton, or, roughly, 6½ cents per pound at smelting-works. Taking the cost of shipment to New York, and the cost of refining, the copper might be laid down in New York at about 12½ cents, a figure which presumably would be considerably reduced by improved appliances, cheaper fuel, etc. The recent developments in some of the mines give reasonable assurance that the output will be sufficient to keep the plant busy. Though apparently loaded down with a very heavy capital, fully five millions of dollars, including purchase price and cost of railroad, the magnitude of the operations of the company will enable it to become a factor in our copper markets, particularly if they company will do its own refining, as it seems inclined to do.

Unless some of the large producers fail to keep up their record—as one of them is now rumored to be doing—their combined product will fully compensate for the falling off of the smaller companies. Their copper, however, to judge from the developments of the past year, will be very largely diverted into other channels, leaving our market tolerably free to the Lake producers. to whom, however, they will be a standing menace.

THE Russian Department of Mines has published statistics of the production of the mining industry of Russia and Finland for the fiscal year ended May 1st, 1882, which furnishes an idea of its development during the past decade. Compared with the year 1872, the figures are:

PRODUCTION OF THE MINERAL INDUSTRY OF RUSSIA AND FINLAND.

	1881.	1872.
Gold, pounds, aver	81,028	84,172
Platinum, " "	6,572	3,322
Silver, " "	20,799	27,154
Lead, net tons	1,087	1,348
Copper, "	3,818	4,105
Spelter, "	5,013	3,397
Tin, "	22	8
Pig-iron, "	517,487	440,091
Wrought-iron, net tons	322,090	295,534
Steel, "	323,323	9,239
Direct castings from blast-furnace, net tons	66,181	36,765
Coal, net tons	3,850,397	1,210,090
Naphtha, "	730,771	27,148
Petroleum, "	231,125	9,361
Manganese ore, net tons	12,387	.....

On the whole, these figures show a satisfactory growth. The gold product of the year 1881 was below the average of 2500 poods in Silesia and the Ural during the past few years, because the season was an unfavorable one. Silver has fallen off because the Altai mines are poorly managed; while the decline in copper is only temporary, the output having again reached normal figures in 1882. Still, Russia is dependent upon outside sources for more than one half of its supply of that metal. The spelter manufacture is almost entirely confined to Poland, and is making satisfactory progress. The oil industry has made very satisfactory advances, though it is predicted that where the needed transportation facilities are provided it will assume much greater proportions.

With all its show, the steel industry is in a precarious condition, because its growth has not been accompanied by a corresponding increase in the make of the raw material, for which the works are almost entirely dependent upon foreign sources. A slight increase in the duty on pig-iron or any hampering of the import of coal would promptly cause this hot-house plant to languish. The Russian coal trade is represented to be embarrassed chiefly by lack of railroad facilities and a short-sighted policy on the part of railroad managers, who can not be made to understand that it would pay them to transport fuel at low rates. In spite of the efforts made in Russia to foster a native mining and metallurgical industry, it does not seem that it is likely to become at an early ate even a very serious competitor of its rivals in its own markets.

A CASE which is of the greatest importance to those holding coal property under title obtained under patent from the United States has just been decided in Colorado by Judge MCCRARY, of the United States Circuit Court, at Denver, Colorado. In that, as well as in almost all of the States and territories of the far West, coal lands are acquired from the government by proof of discovery of their mineral character, and the expenditure of a specified amount of labor in improvement, a patent being issued to the claimant, provided no adverse claims are filed. It is a notorious fact that large tracts of territory have been fraudulently obtained, and yet the innocent third parties who now hold such property by right of purchase from the original claimants have generally been believed to be secure. This hope is now widely dispelled by the decision of Judge MCCRARY in the case of the United States *versus* the Colorado Coal and Town Company, in which the title to 2500 acres of coal lands mostly in Las Animas County, Colo., was in dispute, the present owners being the Colorado Coal and Iron Company, the largest enterprise of its kind in the State. In 1873, sixty-one persons, whom the Judge declares were fictitious, with the possible exception of one JUAN B. MARTINE, a laborer, obtained patents each covering a quarter-section, or in the aggregate 10,000 acres. The evidence shows that none of the lands was occupied by the pre-emptors, nor were they improved in any way, prior to the issuing of the patents, thus showing clearly that the register, IRVING W. STANTON, and the receiver, CHARLES A. COOK, both officers of the Pueblo United States Land-Office, conspired with A. C. HUNT, the person to whom were issued all of the patents in the name of the 61 persons. From HUNT, W. S. JACKSON, a trustee of the Colorado Coal and Town Company, bought them, from which concern they, in time, passed to the Colorado Coal and Iron Company.

One very curious circumstance in connection with the matter is, that E. J. HUBBARD, writing from Trinidad, Colo., under date of November 28th, 1873, called the attention of the General Land-Office to the fact that "coal lands were being entered as agricultural lands by *straw men*, and conveyances made to the procurers of these forgeries (who pretend to be innocent in the matter)." The same party in the same letter wrote: "The register and receiver are charged with complicity in these things." In spite of this warning, the government did not file its bill until January, 1880, when the value of the lands had become more generally appreciated, largely through the exertions of the defendant company; therefore the charge that the negligence of the government officers is due to complicity of persons in office in Washington can not be determined, as it was outside of the question in this case.

The respondents, while partly denying the charge of conspiracy or fraud, rested their case chiefly on the claim that they were innocent third parties. The judge, however, held that, as the patentees were fictitious persons, a grant to them was void, as there could be no conveyance of the title where there was no grantee to take the title. He held, too, that neither the defense of the statute of limitations nor that of laches can be pleaded against the United States.

This decision, if sustained by the Supreme Court of the United States, to which it will be carried, would lead to very serious consequences in the West, endangering the title to a good deal of property. It will be conceded that it is well calculated to stop the scandalous frauds that have led to wholesale stealing of the public lands. But on the other hand, it will cause a good deal of hardship to *bona-fide* purchasers. We trust that, so far as the latter are concerned, some means will be found to lighten their burden.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. Consumers of Graphite.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: We notice that in giving the consumers of graphite in your recent article on graphite, you omitted to make mention of our firm among crucible makers. We have made crucibles for the last twenty years, using Ceylon plumbago. HUSSEY & CO.

PITTSBURG, PA., Nov. 8.

The Population of Johnstown.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: My attention has been called to an article in your paper of the 10th, headed "Among the Iron Workers—Johnstown," in which the writer makes the great mistake of taking the census report of Johnstown proper as containing all the population of the place. Johnstown, containing all the population south of the Conemaugh River, has a little over 8000 people; but the boroughs of Millville, of Cambria, of Prospect, of Conemaugh, which lie around Johnstown borough, and are as much a part of its population as that lying within its legal limits, swell its numbers to over 25,000 people. It is probable that a consolidation will some day be asked for, and the magnitude of our place will be realized.

The Cambria Iron and Steel-Works proper are located in Millville borough, while the works of the Gautier department are located in the borough of Conemaugh, both boroughs being immediately adjacent to Johnstown. In Woodvale borough, which lies just east of Conemaugh borough, are located the flouring mills and woolen mills controlled by the Cambria Iron Company. When the Cambria Works were first established at Johnstown, the population amounted to about 2000. At this day, the total population of Johnstown and surroundings approximates closely to 25,000. Yours truly, D. J. MORRELL.

JOHNSTOWN, PA., Nov. 12.

Amalgamating Flour Gold.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: In answer to your correspondent M. H., in the JOURNAL for October 27th, I will say that pan amalgamation treats flour gold very cheaply and successfully. Notable instances are the ores of Bodie, California; also, the Minas Prietas, of Sonora, Mexico. For cheapness and close work, the latter is a conspicuous success. The company has an office at No. 211 Sansome street, San Francisco, and would doubtless respond to inquiries from your correspondent. MILLMAN.

Nov. 4.

Is Alumina an Acid or a Base in Singulo-Silicates?

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: We know that, in compounds very rich in silica, alumina plays the part of a base; for we have simple silicates of alumina, in which alumina is not only a base but the only base present. We also know that, in compounds low in silica, alumina acts as an acid; for we have not only blast-furnace slags containing as much as 30 per cent of alumina, but also compounds consisting wholly of lime and alumina, in which alumina is the sole acid present, and these are completely fusible. We also have compounds of alumina and magnesia (spinel), of alumina and ferrous oxide (hercynite), and of alumina and zinc oxide (gahnite), which occur well crystallized. We have fusible aluminates of lime, from a tri-aluminate with 64·5 per cent of alumina (which may even be considered as an aluminate of alumina and lime) to a sub-aluminate with only 10 per cent of alumina, corresponding approximately to the formula $Al_2O_3,15CaO$. But we should expect that, in compounds with one and the same ratio between the oxygen of the silica and that of the other oxides present, alumina would play a tolerably uniform part, either acting always as an acid or always as a base.

On this important question, opposite views seem to be held by two of the latest writers on the subject, Mr. A. F. Schneider (in a paper read before the American Institute of Mining Engineers at the Colorado meeting) stating that in his slags, which are singulo-silicates, an *increase* in the percentage of alumina calls for a *decrease* in that of silica and an *increase* in that of the bases; while Mr. O. H. Hahn (in *The Mineral Resources of the United States*, 1883, page 328) states that it demands an *increase* in the percentage of silica, which of course implies a *decrease* in the percentage of the bases. The singulo-silicate of alumina has a higher percentage of silica than have those of iron and of lime, and Mr. Hahn states that, if the increase in the percentage of alumina is not accompanied with a corresponding increase in that of silica, so as to preserve the singulo-silicate relation between the oxygen of the silica and that of the bases, the slag will be undesirably basic.

Mr. Schneider's statements imply that a lower oxygen ratio of silica to base is desirable in aluminous than in non-aluminous slags, or that alumina in these singulo-silicates acts as an acid, which he hints may be the case.

Now, who is right? If we are running successfully with a singulo-silicate slag, and have to increase the percentage of alumina, shall we follow Mr. Schneider, and cut down our silica, or shall we follow Mr. Hahn, and raise it? Which course will give us the best metallurgical results, supposing the other advantages of the two courses to be equal?

May it be that both are right, and that, in calcareous singulo-silicates low in iron, alumina acts as an acid, while in ferruginous ones low in lime it acts as a base? This seems a very important point for all smelters to clearly understand, and more light on it is to be hoped for. Can not some of our plumbic friends elucidate it? With all the experience accumulated in our smelting, it should not be necessary for each metallurgist to test this point for himself by costly experimenting and sleepless nights.

BOSTON, Nov. 9. HENRY M. HOWE.

The Illumination of Mines in Japan.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Regarding the note entitled, "The Ways that are Queer of Japanese Miners," which appeared in your issue of the 8th of September last, I beg your permission to reply to it. It may be construed to mean that all the Japanese miners are occupying most of their time in knocking off the ashes from the bamboo torches, without appreciating the fact that "time is money." I myself was struck by the inconvenience of this kind of lighting a mine, as it causes not only the trouble of knocking off the ashes, and a great waste of time, but also gives off much smoke and more or less vitiates the air of the mines. Fortunately, the use of the torches for the illumination is restricted to some of the northeastern mines, on account of the scarcity of burning-oils, and of the abundance of bamboo in the neighborhood of the mines. In all the other mines, on the contrary, lamps of different types are in general use, and therefore most of the Japanese miners do not really devote their time to the trouble of the bamboo ashes. I am sorry to say that "the engineer who has just returned from Japan" seems to have seen only one or two of the northern mines, which are now using the old way of illumination, and he seems to have concluded that every mine in Japan was in the same condition as those which he inspected.

It is indeed a difficult task to sweep away at once all those disadvantageous methods which we have been accustomed to in all the industrial branches from the time of our ancestors, especially in such a country as Japan, which had so little or almost no communication with the civilized countries. The improvement can only be expected to be a gradual one. In fact, for the last sixteen years, mining and metallurgy have undergone a great many improvements, and the old methods of mining, dressing, and beneficiating the ores are now disappearing day after day.

The above method of illuminating the mines might have already been

Digitized by Google

abolished, if it had happened in the western mines; but the conservatism of the eastern miners, and the abundance of bamboo in that section, have prevented its abandonment until now. Moreover, they cling to the belief that the use of torches improves the ventilation. It happened one time in the fall of the year, at one of the eastern copper mines, that the light did not burn at all from the stopping of the natural ventilation. All the appliances made at that time failed to restore the current. One miner, however, bravely tried to force his way into the mine with a large bundle of burning torches, by which the ventilation was immediately restored. As the miners did not understand the theory of natural ventilation, this cause was imputed by them to the torch itself, without considering its heating action and the consequent change of the temperature of the air between the inside and the outside of the mine.

The engineer of whom you speak reports again that Japanese miners are also great smokers. This is really ridiculous. By what standard of comparison has he determined that they are great smokers? I have never seen Japanese pipes having a bowl the capacity of which is equal to that of an ordinary thimble. The bowl is generally from four tenths to five tenths of an inch in diameter at the mouth, which tapers toward the bottom, like a hollow inverted cone, having the depth of three tenths of an inch. Now, we may just imagine how long it takes to fill such a small bowl with tobacco, and to smoke two whiffs! According to my long experience, it takes no longer than half a minute. If the miners smoke twice successively, it will only be the loss of one minute, which may not disturb them much in their work, although there ought to be no smoking in the working places, especially in coal mines; but I am afraid that they spend much more time in conversation *after* the smoking. If the comparison be made between the Japanese pipes and those which are hanging down from the mouths of German workmen, how many times more do the latter require to fill and clean them?

Permit me to explain briefly in the following the different methods of illuminating the mines which were and are employed in Japan:

The illumination of Japanese mines is done in three ways:

First. By torches. (*a*) Wooden torches. (*b*) Bamboo torches.

Secondly. By lamps of Japanese origin. (*a*) Dish-lamps. (*b*) Shell-lamps.

Thirdly. By lamps of foreign invention. (*a*) The ordinary miner's lamps. (*b*) Safety-lamps.

First. Torches.

(*a*) Wooden torches. There are two kinds of wooden torches. The one called "Tatakigi" (hammered wood) is a common wooden torch, about two feet long, and half an inch thick, the one end of which is hammered so as to be easily lighted. Another kind, called "Shishoku" (paper candle), is a rope made from the long shavings of wood, and moistened with oil. For making this kind of torch, pine or some other wood about one and a half inches wide and three feet long is planed so as to get long shavings as thin as a sheet of paper (hence the name). Many sheets are now rubbed together, so as to soften them, and then made into a loose rope, and lastly moistened with oil. As the rope thus prepared is not stiff enough to be held by hand, a wooden holder provided with an iron hook near the top is used, to which the rope is wound up, the burning end of which is suspended to the hook. It is gradually rolled up toward the top, according to the rate of burning. Both of these wooden torches were formerly used for lighting the underground passages, but not in working places, on account of their smoke.

(*b*) Bamboo torch. It is a small bamboo of a special kind, called "Suzutake" (tin-bamboo), having the diameter of only half an inch. The length varies according to its growth, but, as a rule, it is taken about two feet. Before burning it, the following preparation is necessary: The freshly-cut bamboo is bound up to a bundle of about 2 feet 6 inches in diameter, and placed on the shelves of a smoking-house, where the fire is made on the floor. By this heating operation, the bamboo gives off a tarry sap on the surface, and then it is ready for use. As already mentioned, it is still used in some of the northeastern mines.

Secondly. Lamps of Japanese origin.

(*a*) Dish-lamps. The dishes are either earthenware, porcelain, or iron. The one used in the Sado gold and silver mine was an earthenware dish placed on a clay receptacle in the working places; but it was soon replaced by an iron dish-lamp, provided with a movable hanging rod, whose upper end is bent to a hook. This is called "Kantera," and is now used both for lighting the galleries as well as the working places. When ascending or descending a shaft, the oil is previously poured out into a reservoir, leaving just so much oil behind as is necessary to burn the wick, in order to save the oil which might be lost by the vibration of the lamp. This should, of course, be replaced by the closed foreign lamps. The oil-reservoir carried by each miner is simply a bamboo tube closed at the bottom by the notch, and at the top provided with a stopper.

(*b*) Shell-lamp. The most common lamp which is seen in Japanese mines is what we call "Sazai." It is a shell of about the size of the fist, having a screw-shaped bottom, which gradually widens out toward the mouth. A sketch of this lamp made by me is shown in the memoir *On Mines and Mining of Japan*, written by Prof. C. Netto, and published by the Tokio University. The lamp is either held directly in the hand or, better, by a hanging hook. It has an advantage that the oil does not flow off in case of dropping it down, owing to the spiral shape of its bottom. The origin of the shell-lamp seems to be very old. In a Japanese book, written about 900 A.C., it is mentioned that the "Sazai" lamp is used in the silver mine of the island Tsushima, where silver was first found in Japan in 674 A.C. In some of the western mines, porcelain dishes are used, which are placed on iron rings provided with hanging hooks. The oil used is either rape oil, or an oil extracted from the root of a certain tree; and sometimes fish oil is also used, but it is not desirable, as it burns with a sooty flame and emits a bad smell. The wick is generally the small pith of a sort of rush, four or five pieces of which are burnt together.

Thirdly. The lamps of foreign invention. Although they were lately introduced, they are now rapidly spreading in use. The officers and foremen carry with them always such lamps, as a distinction from the ordinary miners. The safety-lamps are also employed where there is any fire-damp. These kinds of lamps hardly need any further explanation.

Yours respectfully, W. WATANABE.

FREIBERG, SAXONY, Oct. 23.

METALLURGY AND ENGINEERING AT THE BOSTON EXHIBITION.

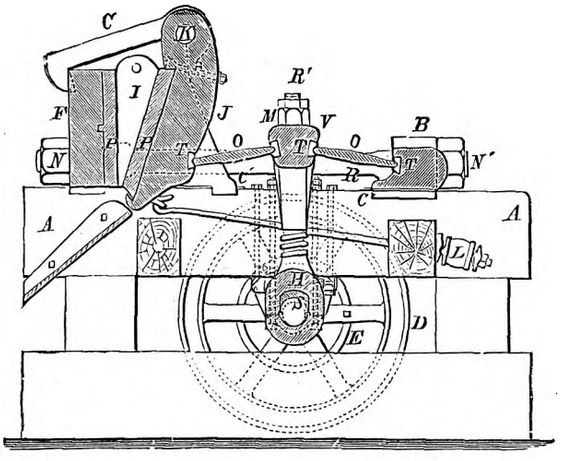
Special Correspondence of the Engineering and Mining Journal.

Steel Castings.—The Chester Steel Casting Company displays many open-hearth steel castings, some of them bent hot, and showing great ductility. They impress one with the very considerable progress which has been made in steel casting, and with the variety of uses to which these important products are now put. The fractures exhibited are solid and free from blow-holes. Some large and very beautiful taps displayed testify highly to the solidity and excellence of these castings, as does also the fact that many of the most important locomotive-works, including the Baldwin Works and others of the very highest standing, are largely supplied with steel castings from Chester for such difficult and important pieces as cross-heads, etc.

Drop-Forgings.—The Billings & Spencer Company has a very impressive display of drop-forgings, many of them of exceedingly complicated form, which it would be next to impossible to forge in the ordinary way. The work of the company is so highly esteemed that it has recently sent to Prussia sets of dies and forging apparatus and skilled drop-forgers to manufacture the bands and other complicated and most difficult pieces for the needle-guns of the Prussian government. This is indeed carrying the war into the enemy's country, when Europe has to send to New England not only for raw materials but actually for skilled labor. Among other exceedingly difficult drop-forgings displayed may be mentioned the sewing-machine shuttles, stocks for taps and dies, set and screw wrenches, very complicated frames for the handles of pistols, lathe-dogs and cutting tools, and the bodies and shells of the Morse twist drills. So extensive has become the use of these drop-forgings that the company now turns out about 20 tons of forgings a month, made mostly from open-hearth steel, employing no less than 34 drops. A single order is shown from the W. A. Wood Mowing and Reaping-Machine Company for 50,000 pitman eyes, which the company is turning out at the rate of 2000 a week; while of sewing-machine shuttles, 35,000 per month is the regular output.

Wooden Rimmed Pulleys.—The large wooden rimmed pulleys of W. W. Carey, of Lowell, Mass., attract considerable attention. The rim is made in segments about one inch broad, firmly spiked and glued together, and is wholly of wood. The hub and arms are of iron, cast in a single piece. The arms proper do not extend quite to the rim, but into the thickened outer end of each arm a set-screw is tapped radially, its axis coinciding with that of the arm proper; in fact, the set-screw is a continuation of the arm, and, by being screwed into or out of it, shortens or increases its effective length. The connection between the rim and the arms is made by screwing these set-screws out radially, away from the hub and toward the rim, against which they firmly jam, so firmly as to make a rigid connection between the rim and the arms. The pulleys are in general faced with leather, to increase their traction.

The evident advantages of these pulleys over ordinary cast-iron ones are: 1. The arrangement of set-screws permits them to be very exactly centered. 2. The leather face has from 30 to 50 per cent higher traction than smooth iron. 3. The danger of serious accidents from the breaking of the pulleys is considerably lessened, if not removed. 4. As they are lighter than cast pulleys, somewhat lighter shafts can be used, at least in the case of pulleys of large diameter, and in those whose diameter bears a large ratio to the width of belt employed. Where the width of the belt is large compared with the diameter of the pulley, the shaft has to be designed to resist the tension of the belt, which not only is often much more severe than the weight of the pulley, but in very many cases in another direction. In places where there are great changes in the amount of moisture in the air, the shrinking and swelling of the wooden rims would probably be a serious inconvenience. These pulleys, faced with leather, are sold at the price of cast-iron pulleys, and it is said that the sales last year amounted to $20,000.



Wrought-Iron Rimmed Pulleys.—Some large wrought-iron rimmed pulleys made under Medart's patent by McMurray & Stoughton, of Hartford, deserve attention. The rim is made in one circular or two semi-circular pieces, according to the size of the pulley, is properly crowned, and is riveted to the cast-iron arms very securely. The company has made these pulleys as large as ten feet in diameter, and is now preparing to make one fifteen feet in diameter. Some 250,000 of these pulleys have been made. When their manufacture was first begun, they were made too light, and a considerable number of breakages occurred; but since the manufacture passed into the present hands, about two years ago, it is claimed that not a single pulley has failed. Among the numerous advantages claimed for these pulleys over cast-iron ones, two should probably be conceded: 1. They are much less liable to break, since the cast-iron portions are not subjected to any thing like such severe cooling strains as are cast-iron pulleys; and if they do break, they are less likely to cause a serious or fatal accident. 2. They are considerably lighter than cast pulleys, thus permitting the use of lighter shafting, hangers, etc., in many cases, and reducing the cost of transportation.

Automatic Speed-Recorder.—The Ashcroft Manufacturing Company exhibits Moscrop's well-designed speed-recorder for engines, shafting, etc. The maker's name is a guarantee of the workmanship of the instrument, which records automatically and continuously the slightest variations of speed. Considerable light might be thrown on the mysterious things which happen in many of our smelting-works at night by the testimony of this instrument and of a continuous blast-pressure recorder, and it has long been a matter of surprise to me that the latter instrument is not largely introduced.

Blake's Challenge Rock-Breaker.—This improved form of our old friend, the Blake crusher, has such marked advantages over the older form that it is likely to supersede it. The old Blake crusher, now called the "Eccentric" crusher, consisted of a fixed jaw *F*, and a moving jaw *J*, actuated by a toggle-joint, all of which were contained and rigidly supported by a very strong cast-iron frame or box. The upper end of the movable jaw was fixed and the lower end was moved by a toggle-joint driven by a pitman *R' H*, somewhat as shown in the accompanying cut. Of course, when the pitman descended, forcing the movable jaw toward the fixed one and crushing the ore between them, there was a tremendous longitudinal strain in the cast-iron frame which contained the two jaws, and against the ends of which the fixed jaw and the outer toggle pressed

Digitized by Google

violently. To resist this pressure, the frame needed great strength, and consequently a large cross-section and great weight per unit of length. To avoid excessive weight, the frame was made short, which necessitated making the toggles *O O* short also. Now, the proportion of the downward pressure of the pitman which is resolved into horizontal pressure against the jaw *J* depends on the angle which the toggles make with each other. If they are nearly parallel with each other, most of the downward pressure of the pitman will be resolved into downward pressure on the bearings T_2 *T*, and but a small portion into horizontal pressure; of course, economical working demands that as much as possible of the power be resolved into useful horizontal pressure and as little as possible into vertical pressure, which is simply rigidly resisted by fixed parts of the machine. Now, if we suppose, for simplicity, that in every case the toggles are approximately in a straight line with each other at the end of the pitman's downward stroke, it should be evident that, for a given length of

stroke of the pitman, the longer the toggles are, the less will be their inclination to each other at the beginning of the stroke. Thus, efficiency demands length of toggles, which in turn requires excessive length and weight of the containing cast-iron frame.

In the "Challenge" crusher, which is represented in the cut, the tensile strains are taken up, not by weak cast-iron, with its puny strength of say 20,000 pounds, perhaps seriously weakened by cooling strains, but by light steel bolts, many times as strong per unit of weight. The upper ends of the jaws are held together by the powerful steel strap *C*, and the bottom of the fixed jaw is held firmly by the strong steel bolts *R*, to the block *B*, against which the outer toggle presses. These bolts are in the plane of the toggles, thus concentrating the material near the line of strain. This arrangement permits us to increase the length of the toggles and thus to get high efficiency, and at the same time to get a very much lighter machine. The upward pressure of the eccentric shaft *S* is taken up by the wooden beams *A A*. It is evident that, as the toggles wear, not only will the opening between the jaws but also the obliquity of the toggles to each other be increased; and as that obliquity increases, so will the horizontal travel of the jaw increase. Now, although in the old or "Eccentric" crusher the opening of the jaw could be adjusted, the obliquity of the toggles could not, except by putting in different-sized toggles; so that in effect the stroke did increase with the wear of the toggles, and if they were allowed to wear too short, the stroke became so long as sometimes to cause strains so great as to break the machine.

In the "Challenge" machine, however, while the opening between the jaws can be regulated by the tension-rods *R*, the obliquity of the toggles, and through it the travel of the jaw, can be adjusted by raising and lowering the pitman-rod *R*, so that any size of opening and any stroke are attainable. While standing up bravely to its work, the Challenge crusher is less absolutely rigid than its predecessor, owing to the resilience of the main tension-bolts and of the beam *A A*, and also to the presence of thin rubber plates inserted between the beam *A* and the fixed jaw and the toggle-block *B*, so that if, as has often happened, a sledge or a lump of wrought iron or of copper gets into the machine, there is enough spring in it to greatly mitigate the sudden irresistible shock which occurs in the "Eccentric" crusher in such an event.

An important feature of the new form of crusher is the lightness of its parts, the heaviest part of a 10 by 7 crusher being 1175 pounds, while the heaviest piece of the 10 by 7 crusher of the older or "Eccentric" pattern weighed 4339 pounds, rather a heavy load for a single mule or llama or canoe to carry. The Dodge crusher and the Wheeler crusher have a slight incidental advantage over the Blake, in the fact that the discharge-opening from their jaws is of constant size, the moving jaw being fixed at the bottom and moving at the top, while the movable jaw of the Blake is pivoted at the top, so that the width of the discharge-opening varies during the stroke by the whole travel of the jaw, this variation in the size of the discharge-opening tending to diminish the uniformity of the size of the product. This is much more than compensated for by the other advantages of the Blake crusher, which is likely to remain long the best crusher in the market for most purposes.

Safety Railroad Crossing and Block System.—The Union Switch and Signal Company, of Pittsburg, exhibits a very interesting full-size working model of its excellent safety crossing, which makes collisions at crossings practically impossible. Even if the engineers of two trains conspired with the operator of the crossing system to produce a *coup de théâtre* by means of a grand and startling collision, they could not accomplish it without first breaking up the machinery with sledge and chisel; so that blowing up the embankment beneath a passing train with dynamite would be a more ready means of accomplishing their object. Not to occupy too much of your space, I will here merely outline the method of protecting a double-track crossing. The manner of applying this apparently very complete system to complicated crossings and junctions, to draw-bridges, etc., is clearly and admirably set forth in the company's pamphlets.

At some distance from the crossing, each track is provided with a switch-rail, to divert trains from the crossing and throw them into a siding. (The siding may be omitted, so that the switch-rail in diverting a train from the crossing will simply derail it, that is, throw it off the track). The switches for all these sidings are operated by levers, which are all collected in a central operating room or cabin, where is also the lever for operating the signals. In addition, each track has two signals, a "distant" and a "home" signal, both of which, as well as the switch, are on that side of the crossing from which the train comes. The "distant" signals are from 1000 to 2000 feet from the central operating cabin; the switches are from 300 to 600 feet from it, according to the grade; and the "home" signals are between the switches and the crossing, about fifty feet from the former. When the crossing is not used, all the switches connect with the sidings, and all the signals, both "distant" and "home," indicate danger. There is but a single lever for all the signals, and this lever can not be moved to indicate safety for any track until its switch has been placed so as to connect that track with the crossing. Nor is it at the option of the operator which signal he shall put at safety; he has no choice in the matter, and the mechanism is so arranged that only the signals of the tracks which are opened into the crossing can indicate safety, or indeed can be moved at all. This arrangement is automatic; there is only one lever for the four signals, and only one mode of moving it to display safety, so that the operator has not to trouble his mind to get the right signal-lever. However, when a train has the "distant" signal, and for any reason stops before or after passing the crossing, the operator can turn that "distant" signal to danger, to prevent other trains from following in on the same track. There is a separate lever for each switch, and these four levers are so interlocked that only the switches of two parallel tracks can lead into the crossing at any one time, the switches of the two opposing tracks necessarily, and in spite of any thing the operator can do, remaining connected into the sidings. As already stated, no safety-signal can be displayed until its track has been connected into the crossing, and then the signal of the opposing tracks must remain at danger, their normal position. But, having displayed a safety-signal for a given track, that track can not be connected into the siding and away from the crossing until its signals, both "distant" and "home," have been turned back to danger. Further, there is an electrical connection (through a short-circuiting caused by the wheels and axles of the train forming an electric connection between the two rails), such that, when a train has been allowed to approach the crossing, the switch of its track having been connected so as to permit it, the train automatically locks all the switches in the position they are in, its own switch connecting into the crossing, and those of the opposing tracks into their sidings; nor can this automatic locking be broken or any switch moved until the last car of that train has actually passed say sixty feet beyond and past the crossings; so that if an operator tried to admit a train from a cross-track so as to cause a collision with one already admitted and past his switch, he could not do it. With this arrangement, we can see how malice, stupidity, or carelessness could block the business of a road and cause annoying delays; but it is hard to see how it could cause an accident. In the model here exhibited, the switches and signals are moved by means of compressed air, which moves the pistons of cylinders placed close to them, its admission being governed by valves actuated by the levers in the cabin. In some instances, hydraulic cylinders are used in place of these pneumatic ones; and in other cases, the movements are effected by means of a series of levers, cranks, and rods.

The same company's *rail circuit block system* is already widely adopted and seems very effective. In it, the signals are so hung that a heavy counterpoise draws them always to "danger," and they can only be brought and held at "safety" by the action of electro-magnets, one of which is connected with each signal, and is magnetized by a gravity cell. If by any means the current from this gravity cell is diverted from the electro-magnet, the latter becomes at once demagnetized, and the counterpoise above referred to, no longer opposed by the magnet, draws the signal to "danger."

The track is divided up into sections, each of a length of say 1000 feet. Each section is insulated from the adjoining ones. In a double-track road, the signal of a given section is placed at the end of that section at which the train enters, and the cell which magnetizes its magnet is at the farther end of the same section. When the section is vacant, the current from the cell passes down one rail to the magnet (thus displaying "safety") and back to the cell along the other rail, the cell and the magnet being each connected by wires with each rail. Now, if a train or a single pair of wheels enters this section, it will short-circuit the current; that is to say, the current will pass from the battery along one rail until it meets a wheel; now it will take the path of least resistance, and pass through the wheels and the axle over to the other rail, and so back to the battery, instead of taking the longer and narrower path through the long fine wire through which it would have to pass to continue its work of magnetizing the electro-magnet. Diverting the current from the magnet destroys its magnetic power. It no longer holds the signal, which the counterpoise, now unresisted, draws to "danger." This state of affairs will continue as long as a single pair of wheel remains on the section. When the last pair leaves the section, the current will now have no short cut offered to it, but will be forced to pass through the electro-magnet, which will draw the signal to "safety," overcoming the weaker attraction of the counterpoise. Thus, as long as a single pair of wheels remains on the section, the signal "danger" will be displayed to all following trains on approaching that section. It is evident that, if a rail breaks so as to destroy the continuity of the track, the current will be broken, the magnet, as before, demagnetized, and the signal drawn by the counterpoise to "danger." In brief, if any thing goes wrong, "danger" is displayed.

Several modifications of this method are shown. In some, the signal and magnet are placed, not at the beginning of the section, but so that they will be seen by the engineer, say 1000 feet before he arrives at that section. In others, two signals and two electro-magnets are placed, one at the beginning of the section, and one say 1000 feet back of it. The latter would then be merely a signal for caution, the former for danger.

In single-track roads, the current of each section operates four signals, one at each end of the section, one a whole section-length back of it, and

Digitized by Google

one a whole section-length beyond it. Thus, when a train is entering a section, danger-signals are displayed two whole section-lengths ahead of it; and just before its engine leaves that section, there will still be danger-signals one section-length before it, and two section-lengths (minus the train-length) behind it. Two trains approaching from opposite directions will be notified of each other's approach while they are still two section-lengths apart, and perhaps much farther; while the hindermost of two trains moving in the same direction will be notified of the presence of the train which precedes it, while they are still at least one section-length apart. (TO BE CONTINUED.)

ON MILL STATISTICS, WITH SPECIAL REFERENCE TO THE EXTRACTION OF THE PRECIOUS METALS.

By C. A. Stetefeldt.

Complete statistics are as essential in metallurgical works as double book-keeping is in a mercantile business. In most European establishments, these statistics are carried out with an amount of labor and care which are unknown here. Still, so far as the percentage of metal extracted is concerned, some very loose customs formerly prevailed. The good old "Hüttenmeister" of the Hartz smelting-works, who used to go on a tour of inspection with a long pipe and in a dressing-gown, really believed that they did not lose any silver in smelting, but even got out more than the amount found by assay. I am told there are smelting-works in Colorado in which the same thing is done: they lose no silver at all, but are content with a yield of 100 per cent. The losses in lead and copper also were invariably given too low. These discrepancies were caused by the so-called "Hüttenremedien" or allowances, and by defective methods of assaying, especially so far as lead and copper were concerned. Such statistics were only in so far of value as they served as comparative standards of the operations performed, as the same blunders were committed over and over again. In recent times, many of these nuisances have been abated, and more accurate methods of assaying have been generally introduced.

In our American silver and gold mills, treating ores by amalgamation or lixiviation, statistics are kept which are sufficiently approximate so far as the cost of reduction and the quantities of materials consumed are concerned; but, in most cases, they are entirely worthless when it comes to the question what percentage of the precious metals has actually been extracted. There are a few exceptions to this rule; for instance, the Manhattan mill. Austin, Nev., where a large portion of the ore reduced is "tribute" or "custom" ore. But even in this case, I am inclined to believe that the results are somewhat overestimated on account of the "allowances." Of course, in taking weight, and in determining the percentage of moisture, the mill can not afford to be on the losing side. The proper way would be to take the weight of the dry ore as it comes from the dry-kiln. But here we are not in any better position, if the taking of weights is left to the laborer who discharges the dry-kiln. In fact, it would be necessary to have in each shift a reliable person attending to nothing else but taking weights. But for such extra labor, nobody is willing to pay.

With what remarkable inaccuracy statistics are kept, and how strangely they have been interpreted, even by prominent mining engineers, the following example will illustrate. I have before me a report by Prof. W. P. Blake, on the Alice mine, Montana, dated November, 1881. In it, he gives a "table showing the assay value of the raw and roasted ore, in silver and gold, of the Alice mine, worked at the company's mill in 1879." The table contains: 1. The ounces of silver and gold in "raw ore battery." 2. The ounces of silver and gold in "roasted ore pulp." 3. The ounces of silver and gold in "tailings." 4. A column with "silver saved." The column "silver saved" is calculated from the silver value of the "roasted ore pulp" and the silver value of the "tailings." Let us see how Professor Blake comments on these statistics. He says: "I regard such a table as this as unique in the history of the metallurgy of silver and gold in the United States. It is a very satisfactory record and exhibition of the work of the Alice Company for the past year. . . ."

His comment should have been: These tables are incomplete and incorrect in more than one respect. 1. They do not contain any chlorination tests, which are essential to show how the roasting process has been conducted. 2. The percentage of silver saved is calculated by comparing the value of the roasted ore directly with the tailings. These values bear no direct relation to each other, as the soluble salts of the roasted ore are leached out from the tailings in the settlers, and the tailings represent concentrated matter compared with the roasted ore. 3. In place of "silver saved," the last column should read "silver remaining in tailings." The silver remaining in tailings does not represent the total loss of silver in milling. Besides, Professor Blake is mistaken in considering these statistics as "unique in the history of metallurgy in the United States." Long before, better and more complete statistics were kept at the Auburn mill, Manhattan mill, Northern Belle mills, and others, in Nevada.

Farther on, Professor Blake indulges in the following remarkable statement: "It is interesting and of some practical importance to note that the working result in the large way in the mill exceeds in the totals the amount which the assay results indicate; . . . . . hence the bullion was in excess $10,329.66, or about $2.50 per ton for the amount worked during that time, namely, 4120 tons. This discrepancy may be due to the difference in the working. The fire-assays, of course, entail a loss in silver, due to the presence of zinc, and perhaps a greater loss than is experienced in roasting and milling. It is not yet clearly experienced, but is a well-ascertained fact, that the product overruns the assays."

These facts are indeed "interesting and of some practical importance." The idea that "the zinc entails a greater loss in assaying than is experienced in roasting and milling" will be a great comfort to the owners of all mills and smelting-works who buy silver ores, and who should pay a premium on ores containing zinc.

Professor Blake's criticism should have been: These facts again prove in what a desultory manner some Western mills keep their statistics. Indeed, to get a yield of bullion $2.50 above the assay value is a most astonishing feat. Granting that the samples have been taken with proper care, and that the assayer's work is reliable, the results show gross negligence in ascertaining the weight and moisture of the ore.

Under the circumstances, it is desirable to have some statistics which show us every day what is actually done in the mill, and to give us at least an approximate idea of the losses in precious metals which take place in roasting. Such statistics I first introduced at the Ontario mill, and they have also been adopted by the Lexington mill and others.

The following determinations are made every day, namely:

1. Pulp-sample contains..... ..... Ounces silver.
   " " " .... Ounces gold.
   " " " .... Per cent salt.
2. Value of raw ore..... ..... Ounces silver.
   " " .... Ounces gold.
3. Car-sample, roasted ore, contains..... Ounces silver.
   " " " ..... Ounces gold.
   " " " ..... Per cent soluble salts.
   " " " ..... Per cent of the silver chloridized.
4. Value of roasted ore after leaching... ..... Ounces silver.
   " " " " " ..... Ounces gold.
5. Tailings..... Ounces silver.
   " .... Ounces gold.
6. Remaining in tailings..... ..... Per cent silver.
   " " " .... Per cent gold.
7. Of the silver remaining in tailings..... .. Per cent present as chloride of silver.

1. Where roasting-furnaces are used, working on the continuous principle, the pulp-sample is best taken where the ore enters the feeding apparatus of the furnace, because here the moisture is most complete. The percentage of salt is determined by leaching 10 gr. with water on a filter, until the filtrate shows no chlorine reaction with silver nitrate. The filter is then dried, and the residue carefully brushed off, and its weight taken.

2. The value of raw ore is calculated from the assays and salt percentage of the pulp-sample.

3. The sample of roasted ore is taken from the cars transporting the ore, after cooling, to the pans or leaching-vats. This sample being moist, must first be made dry. It is best to pass it through a screen and destroy any lumps by rubbing in a mortar. Ten grams are washed with hot water as above. As in amalgamation, chloride of silver is reduced and also cuprous chloride, which latter goes only partially in solution by leaching with water, the result is not absolutely correct, but this error is compensated, to a certain extent, by some soluble salts remaining in the tailings after decanting the settler water. When the silver is extracted by lixiviation, a hyposulphite solution of the same strength as that used in working should be employed for the leaching test in determining the percentage of soluble salts. The chlorination assay is made in the customary manner with sodium hyposulphite.

4. The value of the roasted ore after leaching is calculated from the assays and percentage of soluble salts of the car sample of roasted ore.

5. If tailings are taken from the settlers, the water should be decanted from the sample before the same is put up for drying.

6. The percentage of precious metals remaining in tailings is calculated from the values of the roasted ore after leaching.

7. The tailings very frequently contain chloride of silver. It is advisable to make chlorination tests, if not every day, at least occasionally, especially if the tailings are of higher value than usual.

In case the ore contains gold, besides silver, gold assays need not be made every day. It is sufficient and more accurate to collect say ten assay-buttons, and dissolve them together.

It will be seen that these statistics, which do not cause so much extra labor as appears at first sight, give a most complete insight into the metallurgical working of the mill. We learn, in the first place, that the ore has been mixed with such a percentage of salt as is most advantageous for good chlorination. The chlorination tests show us how the roasting has been conducted. When ore is of such a character that the silver is well chloridized without having to go through the "banking up" process on the cooling-floor, it is of advantage to take also samples, every shift, from the furnace, directly after discharging the ore. This is done at the Manhattan mill. Four chlorination tests are made every day. Samples are taken from the shaft, and from the ore roasted by the auxiliary fire of the Stetefeldt furnace, day-shift and night-shift.

In judging the work of the pans or the leaching-vats, the tailings can not be compared with any other values but those of the roasted ore after leaching with water or sodium hyposulphite solution. To these alone, and to none other, the value of the tailings stands in a direct relation.

Finally, the chlorination test of the tailings informs us about the mechanical condition of the roasted ore, namely, whether the same contained hard and insoluble lumps. Or it shows negligence in conducting the process of amalgamation, or lixiviation, when the roasting was normal.

But besides this, if we only understand reading between the lines, these statistics give us valuable information about the loss of silver which took place in roasting, and herein consists one of their chief merits. To show this, we must enter into a discussion of some length, and will select a special case in which the reasoning can be supported by actual results. We will take ore from the Ontario mine. The Ontario ore contains zinc-blende, galena, fahl-ore (with silver, copper, lead, zinc, antimony, arsenic, and sulphur), iron pyrites, metallic oxides, quartz, and clay. It enters the furnace mixed with salt. After roasting, the following changes have taken place:

The silver is changed mostly to chloride. The salt is mostly changed to sodium sulphate, a variable percentage being left undecomposed. The quartz remains unchanged. From the clay, some valuable aluminium chloride and sulphate are formed. The zinc-blende is principally converted into zinc oxide. A small percentage appears as soluble zinc chloride and sulphate. Galena changes partly to lead oxide, partly to insoluble lead sulphate. The larger portion of the copper in the fahl-ore becomes oxide. Another portion is found as cuprous chloride and as copper sulphate. Iron pyrites becomes peroxide of iron. Antimony and arsenic pass off mostly in fumes, partly they remain as antimoniates and arseniates. The sulphur escapes partly as sulphurous acid; another portion becomes sulphuric acid, which largely remains in the roasted ore in the form of sulphates.

The principal changes in weight of the ore are as follows:

100 salt change to 121¼ sodium sulphate.
100 sulphate in galena and zinc-blende are replaced by 50 oxygen.
100 sulphur in iron pyrites are replaced by 87½ oxygen.

Digitized by Google

100 sulphur in combination with copper in fahl-ore are replaced by 100 oxygen.

100 sulphur in combination with copper in fahl-ore are replaced by 222 chlorine.

100 sulphur in galena, are replaced by 300 sulphuric acid, and oxygen for that portion of galena which changes to lead sulphate. The same increase takes place in the formation of the sulphates of copper and zinc. If an ore contains hydrates and carbonates, the loss in water and carbonic acid will also cause a considerable reduction in weight.

It will be seen that some of these changes have a tendency to increase the weight of the ore after roasting, while others decrease it. If we compare the weight of raw ore, mixed with salt, with its weight after roasting, it may show an increase, especially if a large percentage of salt has been used, and the ore is rich in sulphur. But we obtain an entirely different result by comparing the weight of the raw ore, without salt, with the weight of the roasted ore after leaching out the sodium sulphate, undecomposed salt, and the other soluble salts. This change can be easily ascertained by roasting a known quantity of ore pulp (with salt) in a muffle, and then taking its weight after the soluble salts have been leached out, either with water or with sodium hyposulphite solution, as the case may demand. If, then, a decrease in weight has taken place, the roasted ore, minus soluble salts, should contain, per ton, a proportionately higher amount in ounces of the precious metals, provided no silver has been lost in roasting. If, however, the roasted ore should contain a less per cent of silver per ton than that demanded by its reduction in weight, we can arrive at no other conclusion save this—that silver has been lost in roasting by volatilization. If the weight of the ore has been increased, a similar reasoning holds good.

Even if it should be impossible to roast the ore in the muffle exactly in the same manner as it is done on a large scale, the result will at least be a very close approximation. Another, but more t-dious, method would be to subject the raw ore and the roasted ore to a chemical analysis, and from it calculate the change in weight which has taken place.

The following experiments were carried out for me by Mr. E. H. Russell at the Ontario mill. An average sample of battery-pulp was collected for a period of 35 days. After chloridizing roasting in the muffle, and leaching out the soluble salts with water, 96·3 parts of roasted ore resulted from 100 parts of raw ore. During the same period, the average value of the battery samples was 70 ounces silver per ton. The average percentage in salt was 18·5 per cent. Hence the value of the raw ore was 85·9 ounces per ton. The average value of the car-samples of roasted ore was 67 ounces; the soluble salts, 23·5 per cent. Hence the value of the roasted ore, after leaching out soluble salts, was 87·6 ounces of silver per ton. According to the above roasting test in the muffle, it should have been 89·2 ounces. From this it appears that 1·6 ounces of silver per ton were lost in roasting, or 1·8 per cent of the silver contained in the raw ore. No absolute correctness is claimed for these figures, but they are, no doubt, sufficiently near the truth to be of interest and of practical value.

THE IBRUEGGER CUPOLA.

A new cupola, the invention of G. Ibruegger, of Norden, has been brought out recently in Germany by Dirks & Co., of Lees, and is now being introduced into this country by Mr. E. J. Schmitz, of this city. The reports which come to us from Germany regarding its working are encouraging, to say the least; and though upon first examination it may appear to show the serious drawbacks of being too complicated and too easily liable to excessive repairs, it has features which commend it to the attention of founders and metallurgists. The cupola consists of the usual shaft *A*, below which is a receiving chamber *B*, with arched roof, accessible by the charging-flue *C*, which also fills the office of a preheating chamber for scrap. *N* is an opening for cleaning out the slag, while *F* is a tap-hole for running out the melted pig. *E* is an opening for raking out unconsumed coke. The cupola is charged with pig in the usual way, the upper part of the shaft being, by the way, protected against wear by the wrought-iron frames *H*. Any wrought scrap to be used is run into the preheating chamber *C* through the door *G*. Blast is supplied through the main *L* to the lower series of tuyeres *b*, which, it will be noticed, do not lie in the same plane. The greater portion of the carbonic oxide formed in front of the tuyeres, finding greater resistance to their passage upward through the charge than downward through the holes *a a* connecting the shaft *A* with the receiver *B*, pass down into the atter, where they are supplied with fresh air through the branch of the tuyere-pipe *D* and its flue into the roof of the receiver. In this manner, the receiver *B* is heated, the gases of combustion escaping through the flue *K*, preheating in their way the scrap piled up in the chamber *C*. That portion of the gases of combustion before the lower series of tuyeres which escapes upward is consumed by air blown in through the upper series of tuyeres, the throttle being alternately opened and closed. The molten iron drops through the openings *a a* into the receiver *B*, in which it to some extent undergoes a fining process. Whenever necessary, the scrap is pushed into the bath and stirred. It is claimed that, under the action of the gas in the preheating chamber, it is to some extent carburized.

The principal advantages claimed for the new cupola are that a low grade of pig can be used, Middlesborough No. 3, containing much silicon, but little magauese, being recommended; that a very considerable quantity of wrought scrap may be added, when needed, without impairing the fluidity of the metal; that the removal of the melted iron at once from the shaft permits of the tuyeres being placed at a lower level; and that the thorough utilization of the waste gases saves fuel. In reference to the first point, Messrs. Dirks & Co. state that, when using a mixture of one half of Middlesborough No. 3 and one half of cast scrap, with a small quantity of old rails and wrought scrap, they have made castings bringing a piece from 10 to 15 per cent higher than metal made from a mixture of which No. 1 Scotch was a leading part.

For small castings, an admixture of from 2 to 3 per cent of wrought scrap is recommended, the proportion rising to 10 per cent for castings of medium size, and to 30 per cent and more for large machinery castings. The consumption of fuel is stated to be from 10 to 12 per cent with coke.

THE MINES AT RIO TINTO, SPAIN.—I.

Among the most remarkable mineral deposits known, those of Rio Tinto, Spain, possess more than ordinary interest for Americans, because the company working them is one of the leading competitors in our own markets of the miners of pyrites for sulphuric acid manufacture, and at the same time the one that has during the past few years rivaled our copper producers in placing growing quantities of metal on the markets of the world. An elaborate report by a leading French engineer, M. E. Cumenge, and printed during the current year, throws a flood of light on the present condition and the future of the great mine, and contains many points which deserve the attention of engineers and metallurgists.

The deposits of the Province of Huelva, of which Rio Tinto is one, were known to the ancients, Phœnicians and Romans, who, as evidence of their activity, have left more than 180 miles of workings in the Rio Tinto deposit alone, and accumulated no less than twenty million tons of slags and cinders on the neighboring dumps. A metalliferous zone extends in approximately an east and west direction for a distance of twenty leagues from El Castillo de las Guardias, north of Seville, beyond the Portuguese frontier. It is four leagues wide. Rio Tinto is situated towards the eastern end of the zone, while the mines of the Tharsis Company are located toward the west, there being a series of minor deposits between the two, among them El Castillo, Peña de Hierro, La Cueva de la Mora, Sotill, St. Elmo, La Joja, La Zarga and some others, some of them, like the Buitron mine, being partially exhausted. According to M. Cumenge, the province of Huelva is composed of Carboniferous or culm schists and graywackes plicated by powerful eruptions of granitic rocks forming the distant Sierra Morena. A later period was marked by the appearance of quartz porphyry, while the deposits themselves are attributed to the Permian period by M. Cumenge, who, for some reason not specified, believes them to be the equivalent of the Carboniferous schists of Mansfeld, the sandstones impregnated with copper ores of the Corrège, of the Saar, of the Rhine, and the Ural Mountains. Since the formation of the pyrites deposits, movements have taken place which have caused fissures in the deposits, and the upper portions of the deposits have, under atmospheric action, been converted into iron oxide, forming an "iron hat." To the south of the Rio Tinto deposit, the schists have been covered by a horizontal layer of from 10 to 13 feet of rock, mined as an iron ore under the name of *Mesa de los Pinos*. There are also eruptive rocks, traps, of a more recent date.

The pyrites deposits of this zone are closely related to the porphyries, and are found at the contact of the latter and the rudimentary rocks, or in the latter. M. Cumenge pronounces the Rio Tinto deposit a fissure-vein, and refers to the Comstock to dispel the prejudice against considering deposits of such dimensions true fissure-veins. Neglecting the Vallée vein, on which no work has been done, there are two principal seams of ore, called the North vein and the South vein, the former being 3500 feet and the latter 2500 feet long. Those parts of the South vein which are worked are over 400 feet wide, while at other parts soon to be opened the vein is upward of 300 feet wide. The North vein at some points reaches a thickness of 1600 feet.

The Rio Tinto deposit consists of a compact mass of cupriferous iron pyrites occasionally showing patches of gray copper, blende, and galena. The ore as mined is divided into two classes, by sorting according to its contents of copper, about one quarter of the quantity being exported, while the rest is treated on the spot. Samples are taken from every car of ore loaded, and, the entire sample being crushed, a daily average assay is made. M. Cumenge estimates the general average for the year 1882 at 2·88 per cent of copper. The export ore, 250,000 tons annually, is sold by the Cornish assay, which understates the true percentage by 0·75 to 1·0 unit, so that the actual percentage of copper in this class of ore lies between 3·25 and 3·50 per cent and from 48 to 50 per cent of sulphur. The ore treated on the spot carries on an average 2·50 per cent of copper. The following is a recent analysis of the export ore:

ANALYSIS OF RIO TINTO EXPORT ORE.

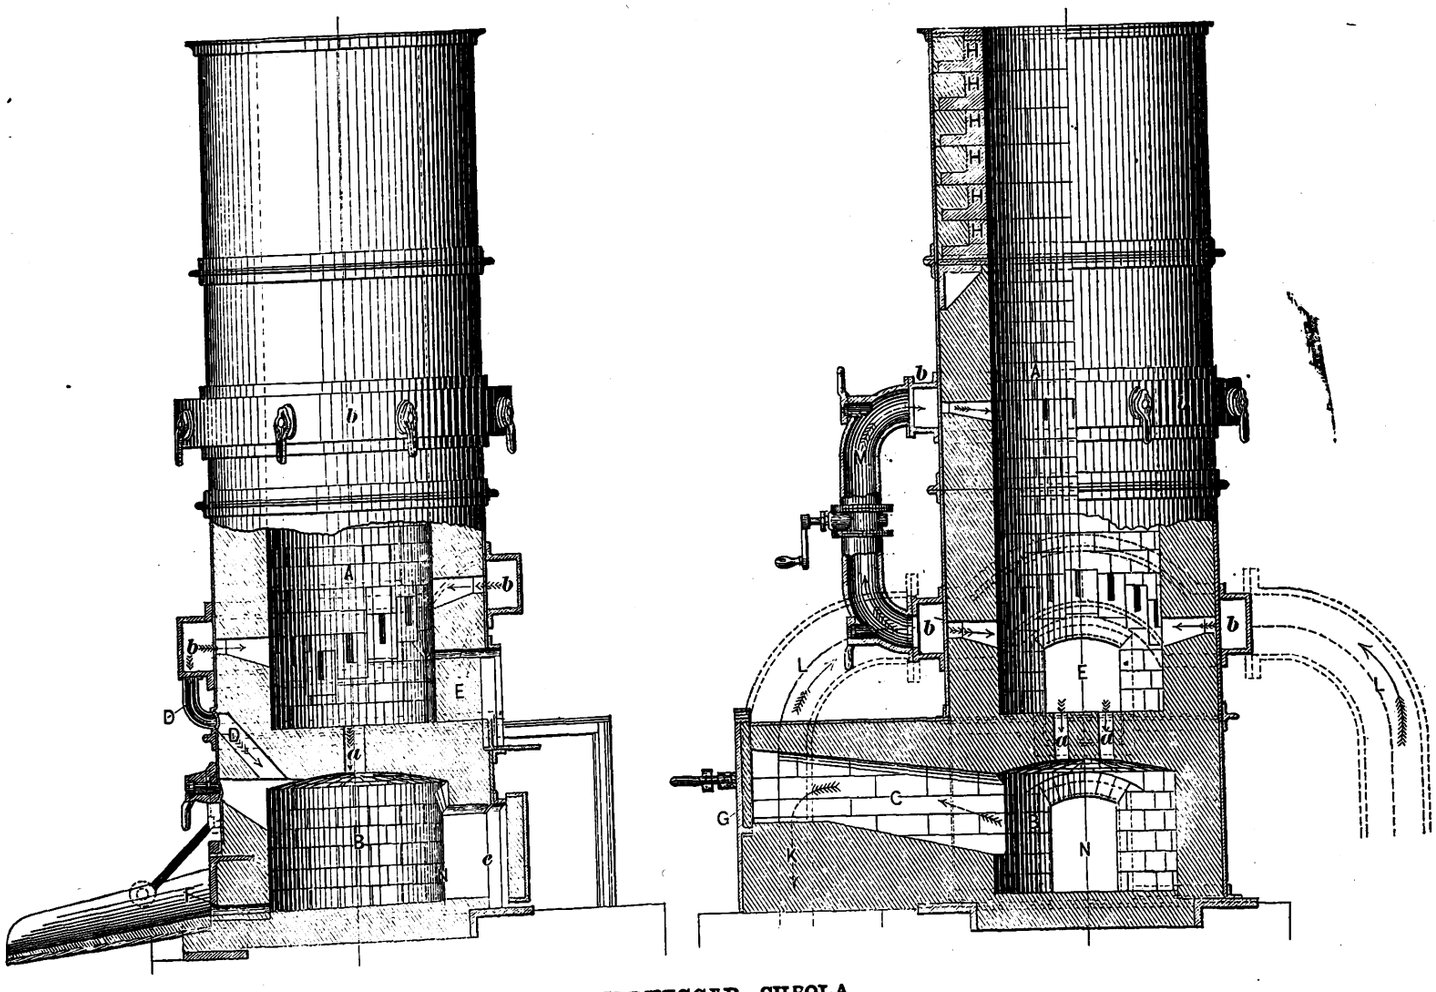
	Per cent.		Per cent.
Sulphur	47·76	Lead	0·10
Iron	43·99	Cobalt	0·05
Copper	3·69	Lime	0·23
Arsenic	0·83	Manganese	0·07
Bismuth	0·37	Silica	1·99
Zinc	0·24	Moisture	0·48

The ore contains traces of selenium and thallium, 40 grams of silver, and 0·892 gram of gold to the metric ton.

Until now, all the estimates of the engineers have referred solely to the mass of ore worked by an open cut, which until a recent date furnished almost all the ore. The ancient workings, which, to a certain depth, were numerous, had evidently the object of mining the seams of richer ore in the mass of average grade, and this fact alone explains the increase in the percentage of copper when virgin ground was opened. Experience has proved that, in taking five millions of tons out of the open cut, almost the entire mass is uniform and essentially composed of compact iron pyrites, with spots of copper pyrites and black sulphide. In the future, however, the fact must be taken into account that the western part of the South vein, known as the San Dionisio lode, is more complex. The copper becomes a more important factor. Pure copper pyrites is not found in spots, but true seams, and other copper minerals become more abundant, so that the average thus far is 4 per cent of copper, and selected lots assay from 7 to 8 per cent. The Rio Tinto Company bases great hopes upon this part of the ground, and has begun great underground workings; and it is a fortunate circumstance that that portion of the San Dionisio ores which are too rich to be worked by the present process carry considerably larger quantities of silica, fitting it better for smelting.

Of the North vein, which is much larger than the South vein, comparatively little can be positively stated, because, though extensive, the workings have hardly more than scratched the deposit. If it be fair to reason from the existence of innumerable Roman pits and the proximity of dumps of slags, the ancients directed their main efforts to this deposit, probably with good reasons. To judge from the quality of the ore taken out of workings now going on, the poor ores of this vein are more porous

Digitized by Google



and better fitted for the treatment by the lixiviation process. Rich ores have also been extracted, and there is reason to believe that the average grade is very nearly the same as that of the ore from the open cut on the South vein. As the company has fourteen millions of tons of ore in sight above the tunnel level in the open cut and in the San Dionisio lode, M. Cumenge does not believe that for the present the subject is one that it is necessary to discuss. .

On the question of the maintenance of the grade in depth, below the 300-foot level, it is only necessary to cite the fact that a bore-hole drilled 250 feet below the lowest workings in the open cut yielded ore running 3·25 per cent of copper on an average. Possibly, the quantity of galena may increase ; but on the other hand, as the silver seems to be associated with it, this will tend to better returns in this respect. In a general way, it may be stated, concerning the percentage of copper in different parts of the deposits, that it increases toward their western extension.

The workings have been begun by starting an open cut on the widest portion of the South vein, which had been opened out on a small scale by shafts and drifts during the time when the deposit was the property of the Spanish government. In order to reach the ore, it was necessary to strip the vein of from 30 to 100 feet in depth of oxide, forming the "iron hat" of the vein, an undertaking rendered necessary by the character of the side-walls and by the importance of carrying up the production to a high figure at short notice. There is no doubt that there is nothing in metalliferous mining in the world to compare with this open cut, which is in its central portion nearly 400 feet wide, all in ore, is about 1600 feet long, and represents a body of ore nearly 300 feet in hight, and which has yielded at the rate of one million tons of ore per annum. It has become evident that mining on such a scale could not be continued without further stripping. The mass of Mount Solomon, near the open cut, is a source of danger to it, and the heroic measure has been adopted to remove the entire hill, made up of decomposed porphyry. Six terraces, each 50 feet high, have been started, and work is pushed day and night. If that plan had not been adopted, it would have been impossible to extract, by the open cut, a quantity of ore above the main tunnel amounting, according to M. Cumenge's estimate, to four millions of tons, or eight years' work, if the rate of extraction be maintained equal to that of 1882, when the quantity of ore taken from the open cut was 500,000 tons. M. Cumenge, by close measurements, computes the average surface of the section of the ore-body in the open cut at 3318 square meters, the average section of the stripping already done being 6875 square meters, and of the stripping to be done 3375. On the 1st of January, 1882, 2,578,125 cubic meters of dead-rock were to be removed to make 4,900,000 tons of ore accessible. In all, when exhausted, the open cut will have furnished 9,600,000 tons of ore, for which about 3,000,000 tons of dead-rock will be removed. The actual cost of stripping in 1882 was 0·43 franc per ton of ore. M. Cumenge, however, for safety's sake, places it at 1 franc per ton.

A study of the conditions affecting the San Dionisio lode proved that it was impossible to mine in the same manner. Though the large number of Roman pits and a long drainage tunnel driven by them indicated favorable ground, there was nothing upon which to base an estimate of the width of the deposit or the grade of the ore. Systematically conducted borings were begun in 1879 with an American diamond rock-drill, which threw light upon the thickness of the barren cap of oxide of iron and the grade of the ore at different points. After three years' work, the following has been accomplished on the San Dionisio lode: There are in a line four hoisting-shafts and three ventilating-pits, No. 5, the main shaft, being equipped with a plant capable of handling a daily output of from 1000 to 1200 tons. It has passed through about 150 feet of the "iron hat" to reach the ore, in which it has been sunk about 175 feet. The lowest workings on the San Dionisio vein have been connected with the level of the tunnel under the open cut, and there are now 8500 feet of gallery 13 feet square, in which the same locomotives pass to and fro which run on the railroad connecting the mines with the port of Huelva. While driving this level in the ore at the rate of about 7 feet per day with rock-drills, it yielded 120 tons per day, and it will be readily understood that these underground operations will furnish as much ore annually as the open cut, when it is stated that a cross-cut run 285 feet did not reach the north wall. Independently of the underground railroad mentioned, the shafts are connected above ground by a railroad running both to the coast road and to the ore-treating grounds. M. Cumenge estimates the stock of ore opened out by these underground workings on the San Dionisio vein at ten millions of tons.

The North vein has been attacked from the east end by a tunnel 2000 feet long, and nine pits, two of them supplied with powerful machinery, have been sunk on it. No. 1 struck ore at a depth of about 120 feet, so that there are 250 feet of it above the level of the Rio Tinto village depot. The vein is at points more than 1300 feet thick and more than 6000 feet long, so that M. Cumenge's estimate of 120,000,000 of tons above that level seems moderate. A double-track tunnel is now driving from Rio Tinto through the porphyry of Mount Solomon toward the North vein, to be completed probably in five years.

THE IBRUEGGER CUPOLA.

THE WORD "TON" IN THE TARIFF ACTS.—The Treasury Department has decided that the word "ton," wherever used in the Tariff acts, should be construed to be the ton avoirdupois—that is, 2240 pounds.

A PLEA FOR PURE SCIENCE.*†

(*Concluded from page* 298.)

Is it possible that any of our four hundred colleges and universities have love enough of learning to unite with each other and form larger institutions? Is it possible that any have such a love of truth that they are willing to be called by their right name? I fear not; for the spirit of expectation, which is analogous to the spirit of gambling, is strong in the American breast, and each institution which now, except in name, slumbers in obscurity, expects in time to bloom out into full prosperity. Although many of them are under religious influence, where truth is inculcated, and where men are taught to take a low seat at the table in order that they may be honored by being called up higher, and not dishonored by being thrust down lower, yet these institutions have thrust themselves into the highest seats, and can not probably be dislodged.

But would it not be possible to so change public opinion that no college could be founded with a less endowment than say $1,000,000, or no university with less than three or four times that amount? From the report of the commissioner of education, I learn that such a change is taking place; that the tendency toward large institutions is increasing, and that it is principally in the West and Southwest that the multiplication of small institutions with big names is to be feared most, and that the East is almost ready for the great coming university.

The total wealth of the four hundred colleges and universities in 1880 was about $40,000,000 in buildings, and $43,000,000 in productive funds. This would be sufficient for one great university of $10,000,000, four of $5,000,000, and twenty-six colleges of $2,000,000 each. But such an idea can of course never be carried out. Government appropriations are out of the question, because no political trickery must be allowed around the ideal institution.

In the year 1880, the private bequests to all schools and colleges amounted to about $5,500,000; and although there was one bequest of $1,250,000, yet the amount does not appear to be phenomenal. It would thus seem that the total amount was about five million dollars in one year, of which more than half is given to so-called colleges and universities. It would be very difficult to regulate these bequests so that they might be concentrated sufficiently to produce an immediate result. But the figures show that generosity is a prominent feature of the American people, and that the needs of the country only have to be appreciated to have the funds forthcoming. We must make the need of research and of pure science felt in the country. We must live such lives of pure devotion to our science that all shall see that we ask for money, not that we may live in indolent ease at the expense of charity, but that we may work for that which has advanced and will advance the world more than any other subject, both intellectually and physically. We must live such lives as to neutralize the influence of those who in high places have degraded their profession, or have given themselves over to ease, and do nothing for the science which they represent. Let us do what we can with the present means at our disposal. There is not one of us who is situated in the position best adapted to bring out all his powers, and allow him to do most for his science. All have their difficulties, and I do not think that circumstances will ever radically change a man. If a man has the instinct of research in him, it will always show itself in some form. But circumstances may direct it into new paths, or may foster it so that what would otherwise have died as a bud now blossoms and ripens into the perfect fruit.

Americans have shown no lack of invention in small things; and the same spirit, when united to knowledge and love of science, becomes the spirit of research. It is useless to attempt to advance science until one has mastered the science; he must step to the front before his blows can tell in the strife. Furthermore, I do not believe any body can be thorough in any department of science without wishing to advance it. In the study of what is known, in the reading of the scientific journals, and the discussions therein contained of the current scientific questions, one would obtain an impulse to work, even though it did not before exist. And the same spirit which prompted him to seek what was already known would make him wish to know the unknown.

As I remarked before, the investigator in pure science is usually a professor. He must teach as well as investigate. It is a question which has been discussed in late years, whether these two functions would better be combined in the same individual, or separated. It seems to be the opinion of most, that a certain amount of teaching is conducive, rather than otherwise, to the spirit of research. I myself think that this is true, and I should myself not like to give up my daily lecture. But one must not be overburdened. I suppose that the true solution, in many cases, would be found in the multiplication of assistants, not only for the work of teaching but of research. Some men are gifted with more ideas than they can work out with their own hands, and the world is losing much by not supplying them with extra hands. Life is short: old age comes quickly, and the amount one pair of hands can do is very limited. What sort of shop would that be, or what sort of factory, where one man had to do all the work with his own hands? It is a fact in nature, which no democracy can change, that men are *not* equal—that some have brains, and some hands. And no idle talk about equality can ever subvert the order of the universe. I know of no institution in this country where assistants are supplied to aid directly in research. Yet why should it not be so? And even the absence of assistant professors and assistants of all kinds, to aid in teaching, is very noticeable, and must be remedied before we can expect much.

As stated before, men are influenced by the sympathy of those with whom they come in contact. It is impossible to immediately change public opinion in our favor; and indeed, we must always seek to lead it, and not be guided by it. For pure science is the pioneer who must not hover about cities and civilized countries, but must strike into unknown forests, and climb the hitherto inaccessible mountains which lead to and command a view of the promised land—the land which science promises us in the future; which shall not only flow with milk and honey, but shall give us a better and more glorious idea of this wonderful universe. We must create a public opinion in our favor, but it need not at first be the general public. We must be contented to stand aside, and see the honors of the world for a time given to our inferiors; and must be better contented with the approval of our own consciences, and of the very few who are capable of judging our work, than of the whole world beside. Let us look to the other physicists, not in our own town, not in our own country, but in the whole world, for the words of praise which are to encourage us, or the words of blame which are to stimulate us to renewed effort. For what to us is the praise of the ignorant? Let us join together in the bonds of our scientific societies, and encourage each other, as we are now doing, in the pursuit of our favorite study; knowing that the world will some time recognize our services, and knowing, also, that we constitute the most important element in human progress.

But danger is also near, even in our societies. When the average tone of the society is low, when the highest honors are given to the mediocre, when third-class men are held up as examples, and when trifling inventions are magnified into scientific discoveries, then the influence of such societies is prejudicial. A young scientist attending the meetings of such a society soon gets perverted ideas. To his mind, a molehill is a mountain, and the mountain a molehill. The small inventor or the local celebrity rises to a greater hight, in his mind, than the great leader of science in some foreign land. He gauges himself by the molehill, and is satisfied with his stature; not knowing that he is but an atom in comparison with the mountain, until, perhaps, in old age, when it is too late. But if the size of the mountain had been seen at first, the young scientist would at least have been stimulated in his endeavor to grow.

We can not all be men of genius; but we can, at least, point them out to those around us. We may not be able to benefit science much ourselves; but we can have high ideals on the subject, and instill them into those with whom we come in contact. For the good of ourselves, for the good of our country, for the good of the world, it is incumbent on us to form a true estimate of the worth and standing of persons and things, and to set before our own minds all that is great and good and noble, all that is most important for scientific advance, above the mean and low and unimportant.

It is very often said, that a man has a right to his own opinion. This might be true for a man on a desert island, whose error would influence only himself. But when he opens his lips to instruct others, or even when he signifies his opinions by his daily life, then he is directly responsible for all his errors of judgment or fact. He has no right to think a molehill as big as a mountain, nor to teach it, any more than he has to think the world flat, and teach that it is so. The facts and laws of our science have *not* equal importance, neither have the men who cultivate the science achieved equal results. One thing is greater than another, and we have no right to neglect the order. Thus shall our minds be guided aright, and our efforts be toward that which is the highest.

Then shall we see that no physicist of the first class has ever existed in this country, that we must look to other countries for our leaders in that subject, and that the few excellent workers in our country must receive many accessions from without before they can constitute an American science, or do their share in the world's work.

But let me return to the subject of scientific societies. Here, American science has its hardest problem to contend with. There are very many local societies dignified by high-sounding names, each having its local celebrity, to whom the privilege of describing some crab with an extra claw, which he found in his morning ramble, is inestimable. And there are some academies of science, situated at our seats of learning, which are doing good work in their locality. But distances are so great that it is difficult to collect men together at any one point. The American Association, which we are now attending, is not a scientific academy, and does not profess to be more than a gathering of all who are interested in science, to read papers and enjoy social intercourse. The National Academy of Sciences contains eminent men from the whole country, but then it is only for the purpose of advising the government freely on scientific matters. It has no building, it has no library; and it publishes nothing except the information which it freely gives to the government, which does nothing for it in return. It has not had much effect directly on American science; but the liberality of the government in the way of scientific expeditions, publications, etc., is at least partly due to its influence, and in this way it has done much good. But it in no way takes the place of the great Royal Society or the great academies of science at Paris, Berlin, Vienna, St. Petersburg, Munich, and, indeed, all the European capitals and large cities. These, by their publications, give to the young student, as well as the more advanced physicist, models of all that is considered excellent; and to become a member is one of the highest honors to which he can aspire, while to write a memoir which the academy considers worthy to be published in its transactions excites each one to his highest effort.

The American Academy of Sciences in Boston is perhaps our nearest representation of this class of academies; but its limitation of membership to the State deprives it of national character.

But there is another matter which influences the growth of our science.

As it is necessary for us still to look abroad for our highest inspiration in pure science, and as science is not an affair of one town or one country, but of the whole world, it becomes us all to read the current journals of science and the great transactions of foreign societies, as well as those of our own countries. These great transactions and journals should be in the library of every institution of learning in the country, where science is taught. How can teachers and professors be expected to know what has been discovered in the past, or is being discovered now, if these are not provided? Has any institution a right to mentally starve the teachers whom it employs, or the students who come to it? There can be but one answer to this; and an institution calling itself a university, and not having the current scientific journals upon its table or the transactions of societies upon its library-shelves, is certainly not doing its best to cultivate all that is best in this world.

We call this a free country, and yet it is the only one where there is a direct tax upon the pursuit of science. The low state of pure science in our country may possibly be attributed to the youth of the country; but a direct tax, to prevent the growth of our country in that subject, can not be looked upon as other than a deep disgrace. I refer to the duty

* Abstracts from an address of H. A. Rowland, of Baltimore, Md., Vice-President of Section B, American Association for the Advancement of Science.

† In using the word "science," I refer to physical science, as I know nothing of natural science. Probably my remarks will, however, apply to both, but I do not know.

Digitized by Google

upon foreign books and periodicals. In our science, no books above elementary ones have ever been published, or are likely to be published, in this country; and yet every teacher in physics must have them, not only in the college library, but on his own shelves, and must pay the government of this country to allow him to use a portion of his small salary to buy that which is to do good to the whole country. All freedom of intercourse which is necessary to foster our growing science is thus broken off; and that which might, in time, relieve our country of its mediocrity, is nipped in the bud by our government, which is most liberal when appealed to directly on scientific subjects.

In conclusion, let me say once more, that I do not believe that our country is to remain long in its present position. The science of physics, in whose applications our country glories, is to arise among us, and make us respected by the nations of the world. Such a prophecy may seem rash with regard to a nation which does not yet do enough physical work to support a physical journal. But we know the speed with which we advance in this country: we see cities springing up in a night, and other wonders performed at an unprecedented rate. And now we see physical laboratories being built, we see a great demand for thoroughly trained physicists, who have not shirked their mathematics, both as professors and in so-called practical life; and perhaps we have the feeling, common to all true Americans, that our country is going forward to a glorious future, when we shall lead the world in the strife for intellectual prizes as we now do in the strife for wealth.

But if this is to be so, we must not aim low. The problems of the universe can not be solved without labor; they can not be attacked without the proper intellectual as well as physical tools; and no physicist need expect to go far without his mathematics. No one expects a horse to win in a great and long race who has not been properly trained; and it would be folly to attempt to win with one, however pure his blood and high his pedigree, without it. The problems we solve are more difficult than any race; the highest intellect can not hope to succeed without proper preparation. The great prizes are reserved for the greatest efforts of the greatest intellects, who have kept their mental eye bright and flesh hard by constant exercise. Apparatus can be bought with money, talents may come to us at birth; but our mental tools, our mathematics, our experimental ability, our knowledge of what others have done before us, all have to be obtained by work. The time is almost past, even in our own country, when third-rate men can find a place as teachers, because they are unfit for every thing else. We wish to see brains and learning, combined with energy and immense working-power, in the professor's chair; but, above all, we wish to see that high and chivalrous spirit which causes one to pursue his idea in spite of all difficulties, to work at the problems of nature with the approval of his own conscience, and not of men before him. Let him fit himself for the struggle with all the weapons which mathematics and the experience of those gone before him can furnish, and let him enter the arena with the fixed and stern purpose to conquer. Let him not be contented to stand back with the crowd of mediocrity, but let him press forward for a front place in the strife.

The whole universe is before us to study. The greatest labor of the greatest minds has only given us a few pearls; and yet the limitless ocean, with its hidden depths filled with diamonds and precious stones, is before us. The problem of the universe is yet unsolved, and the mystery involved in one single atom yet eludes us. The field of research only opens wider and wider as we advance, and our minds are lost in wonder and astonishment at the grandeur and beauty unfolded before us. Shall we help in this grand work or not? Shall our country do its share, or shall it still live in the almshouse of the world?

THE WORK OF THE ORDNANCE BUREAU.

General S. V. Benét, Chief of Ordnance, has submitted to the Secretary of War a report from which we cull the following data:

Under the specific provisions of the act making appropriations for fortifications, etc., approved March 3d, 1883, contracts have been made as follows: For converting fifty ten-inch Rodman smooth-bore guns into eight-inch rifles, by lining with a coiled wrought-iron tube; for making two twelve-inch cast-iron breech-loading rifles, one of which is to be lined, as far as the trunnions, with a steel tube wrapped with wire; for making one twelve-inch cast-iron mortar, banded with steel hoops; for making one ten-inch cast-iron breech-loading rifle, wrapped with steel wire, and one twelve-inch cast-iron breech-loading rifle, tubed, and banded with steel hoops; for the tubes, hoops, etc.; for one eight and one ten-inch steel rifle; for testing the "devices for breech-loading guns," submitted by H. F. Mann and Col. Theodore Yates; and twenty-five carriages for fifteen-inch smooth-bore guns have been ordered to be altered to permit the use of increased powder charges. In the purely experimental guns in the above list, with one exception, steel is used wholly or in part in the construction. Whether or not gun steel, in suitable masses and of the requisite quality, could be procured in this country, had first to be considered. In order to put the wants fairly and squarely before the steel manufacturers of the United States, a circular letter inclosing drawings and giving the weights and dimensions of the steel forgings for an eight-inch "breech-loading rifle and a twelve-inch" muzzle-loading rifle mortar, desired for the armament of fortifications, was freely distributed to more than twenty of the principal steel-works in this country. The replies to this letter were, with one or two exceptions, adverse to undertaking such work, arising, the Chief of Ordnance presumes, from want of skill and knowledge in the treatment of steel for gun construction and from the want of the requisite plant to perfect the forgings. General Benét says the conclusion reached was, that the plant or the experience in this country can not as yet produce the steel forgings for tube and jacket for so large a gun as an eight-inch caliber. The tubes and jackets required for the eight and ten-inch steel guns have therefore been ordered from Sir Joseph Whitworth & Co., England.

The steel hoops required for the banded guns, being of comparatively small mass and readily produced from an ordinary tire-mill, their manufacture has been undertaken by the Midvale Steel Company, of Philadelphia. Three experimental hoops were ordered from this company for test, in order to ascertain how nearly it could come up to the requirements of the department's circular letter. Two of these hoops were of the largest scale that will be required for the experimental guns, and one was annealed after rolling, while the other was oil-tempered and annealed. The third hoop was hammered and oil-tempered, being of the size required for the smaller hoops of the eight-inch gun, which are not sufficiently large to admit of being rolled in the mill at the Midvale Works. The results obtained from the mechanical tests of these hoops, both by traction and by hooping tests, show that they are fully equal in quality to the best hoops of European manufacture. The success attained in the fabrication of these hoops reflects credit on the manufacturers, and testifies to their knowledge, both of the qualities requisite in gun hoops and the best methods of manufacture and treatment for producing them. Under the provisions of the appropriation act to make and test a cast-iron gun, banded with steel, it was at first thought best, on account of its greater simplicity, to make a twelve-inch gun in the Italian system; but unfavorable reports having been received of the behavior of the Italian twelve-inch guns when chambered for charges of 230 pounds, that system was abandoned for the French.

As regards the twelve-inch mortars, cast-iron hooped, experiments are already in progress determining the most suitable rifling and projectiles. The results thus far obtained are fair, and encourage the hope that, with our service projectiles, a good degree of accuracy may be realized from a muzzle-loading rifled mortar. It is recommended that the conversion of ten-inch smooth-bores into muzzle-loading eight-inch rifles be continued. The results of trial show that the eight-inch rifle has sufficient power to penetrate wrought-iron armor eight inches thick at 1000 yards, and this will include that of more than one half of the armored vessels of the world. For places where the depth of water will only admit vessels of light draught and of comparatively thin armor, and for secondary positions in more important places, this gun will fulfill all the conditions of a good defense. It is also recommended to utilize our 300 fifteen-inch smooth-bore guns by supplying the carriages with hydraulic buffers to absorb the recoil, and thus enable us to use the heaviest charges. The projectile energy of this gun has been largely increased, and renders it not only efficient for secondary purposes, but a very formidable weapon even in our most important harbors.

The Gun Foundry Board has visited the principal steel and iron-works in this country and great steel-works and gun factories of Europe. It is hoped that it will be able to submit to Congress such a strong and full report and make such definite recommendations that Congress will be able to take prompt action toward providing for the country's great want in suitable facilities and plant for the manufacture of heavy ordnance.

The report concludes with a recommendation that the expense of testing iron, steel, and other materials for industrial purposes by the United States testing-machine at the Watertown Arsenal be borne by the United States. The Chief of Ordnance is of the opinion that all that should be required of the Society of Civil Engineers is the preparation of a programme for a series of tests; the purchase and preparation of material and the making of the tests to be paid out of moneys appropriated by Congress.

FURNACE, MILL, AND FACTORY.

The Catasauqua Manufacturing Company has made a reduction of ten per cent upon the wages of all employés.

The E. & G. Brooke Iron Company, of Birdsboro', is erecting at its No. 2 furnace a Taylor Langdon ore-roaster, being the second one erected in the State.

The ground is staked off for the erection of the mill of the new Chartiers Iron and Steel Company, Limited, at Mansfield, O., and building will soon be commenced.

P. H. Laufman & Co.'s iron-works at Apollo, Armstrong County, Pa., have been consolidated with the Volta Galvanizing Works of Pittsburg. The concern is now a joint-stock company with a capital of $300,000. The plant at Apollo will be enlarged. Additional anneal-boxes and puddling-furnaces are building, and the firm expects to put in batteries for the galvanizing of sheet iron. The mill is partially operated with natural gas, and more wells are drilling.

The new light rail-mill and the two new Siemens gas-furnaces of the St. Louis Bolt and Iron Company, at East St. Louis, will be started up next week.

The judges of the United States Court in Illinois have sustained the validity of the Washburn & Moen barb-wire patents, while the United States Court for the Eastern District of Missouri gave an opposite decision; and as a result of this conflict of high judicial opinion, it is said there will be an exodus from Illinois of its barb-wire manufacturers, who are expected to locate in Missouri. Several very large factories are now in operation at Joliet, Ill., and it is stated that they will shortly be removed to Missouri, and that their example will certainly be followed by the other Illinois manufacturers of barb-wire. The names of the firms employed in this business in Joliet are, the Lambert Bishop Wire-Fence Company, W. J. Adams, the Ashley Wire Company, Schaeffer & Vanfleet, Klemfelder & Dilman, Kraff, Gross & Co., J. W. Watkins, Barb-Fence Company, and the Lockstitch Fence Company. These factories employ about 1000 men and represent a large amount of capital. Chicago, De Kalb, and Joliet are the three largest markets for barb-wire fences in the West. The factory of J. L. Elwood, at De Kalb, is the largest of these concerns. There are about twenty manufactories in all in the State of Illinois, and the removal of most of them into Missouri would be a matter of no small importance. The dealers in St. Louis claim, however, that the market is already overstocked with the wire fencing, and that it would not pay any new factories to start here. Whatever may be the final outcome of the affair, it seems certain that Washburn will not be able in future to obtain any thing like so large a royalty on his patents as he has in the past.

On the 9th inst., the Scranton Steel Company made sixty heats in eleven hours and forty-three minutes, a little better that twelve heats per hour. This work is worthy of record, because, so far as known, this number of heats has never been equaled in that length of time, anywhere in the world, with two converters. It is also worthy of note that one of the converter bottoms used made forty-two heats, which also, so far as known, beats the record to date.

The sheriff, November 15th, levied on Reis Brothers' sheet-iron mill at Newcastle, Pa., to satisfy a judgment for $10,000 held by Cleveland persons. The exact liabilities can not be ascertained, but they will not exceed $50,000.

The Norton Iron-Works, rolling-mill, and nail-mill, in Ashland, Ky., were burned November 14th. The loss is $200,000.

The nail factory of Brown, Bonnell & Co., is running to its full capacity.

The Black Band Iron and Coal Company, which owns some 4000 acres of land on Davis Creek, in the Kanawha Valley, has just started a new blast-furnace in that locality. The iron ore it reduces is taken from the property. One is a four-foot vein of black band, yielding 46 per cent of metallic ore. Another is brown hematite, or rather a carbonate, of an average thickness of three feet, and yielding, in its raw state, about 45 per cent of metallic iron. The iron is said to be very fine for foundry use. The company makes coke from its own coal. The furnace is 48 feet high, with a 10-foot bosh. Its capacity is 25 tons in twenty-four hours, and the cost is not over $13 a ton.

Digitized by Google

A dispatch from Milwaukee, Wis., dated November 15th, says that the Bay View Fish-Plate Mill and the North Chicago Rolling-Mill Company closed yesterday, throwing several hundred men out of employment. The shut-down was owing to a lack of orders.

The Cleveland Rolling-Mill Company's steel-works will shut down for repairs about December 1st, which will render necessary the closing of the rail-mills and the banking of the blast-furnaces. The wire-mills will remain in operation. The poor state of trade explains the stoppage. President Chisholm, in an interview, stated: "We have concluded not to continue to make rails at a loss." Other iron-works here will follow this example, and either shut down or largely reduce their force of employés.

Henry R. Worthington, the well-known firm manufacturing pumping machinery, has established a branch office in San Francisco, at No. 30 First street.

The Westinghouse Machine Company, of Pittsburg, reports a remarkable activity in the demand for its automatic engine. During the month of October, it manufactured and shipped a total of seventy-three engines, representing a product of nearly $50,000. The new orders during the same month aggregated over 2000 horse-power. Among the prominent orders were: The Philadelphia & Reading Coal and Iron Company, one 80 horse-power, one 65 horse-power, two 50 horse-power, and one 40 horse-power; the New York & Brooklyn Electric Light Company, four engines of 50 horse-power each; the Atnoux Electric Light Company, of Cleveland, two of 65 horse-power; the Brush Electric Light and Power Company, of Savannah, two of 50 horse-power; the Butte Electric Light Company, Butte, Montana, two of 50 horse-power; the Brush-Swan Electric Light Company, of Cheyenne, 65 horse-power; the Brush Electric Light Company, of Buffalo, 50 horse-power; the Electric Light Company, of Decatur, Ill., 50 horse-power. In general manufacture, the Arthurs Coal and Lumber Company, Hemlock, Pa., 125 horse-power; Miller, Dubrul & Peters Manufacturing Company, Cincinnati, 80 horse-power; the Pacific Rolling-Mill Company, San Francisco, Cal., 65 horse-power; E. Stinson & Co., Baltimore, Md., wheel factory, 50 horse-power; McKinney Manufacturing Company, Alleghany City, 50 horse-power; William Broadhead & Sons, Jamestown, N. Y., worsted mills, 30 horse-power; the Senghi Woolen Mills, Yokohama, Japan, 20 horse-power; and about thirty others of various sizes from 10 to 50 horse-power.

The New Jersey & Sonora Reduction Company, of Newark, N. J., composed of Senator McPherson, Col. C. Meyer Zulick, Surrogate; Mr. Packer, of the Lehigh Valley Railroad; Willard Richards, and J. F. Howland, banker, has closed a contract with the Pacific Iron-Works, Rankin, Brayton & Co., San Francisco, for the erection at Nacasari, Sonora, Mexico, of a complete copper smelting plant of 60 tons daily capacity, with the Pacific water-jacket copper smelting-furnaces. This plant will be in running order in ninety days, and will work the Cobriza ores, which are reported very rich by Mr. William A. Farrish, the well-known mining engineer, now at the Carlisle mine, Grant County, New Mexico.

The Tennessee Coal, Iron and Railroad Company, which owns two furnaces at South Pittsburg and a third at Cowan, has lately completed a railroad from its furnaces to its extensive ore and coal mines, giving it ready command of unlimited supplies of ore and fuel. The company owns altogether over 120,000 acres of land, rich with ores of best varieties, and employs nearly 2000 men. Its output of coal is about 600 tons a day, and its production of coke 500 tons a day, which is consumed in its furnaces. Its furnaces at South Pittsburg have a capacity of 200 tons of pig-iron a day, and its Sewanee furnace, at Cowan, a capacity of 85 tons daily.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY.

HENDRICKS.—This mine, which is leased to the Tombstone Mining and Milling Company, is producing ten tons of lead ore per day, which is shipped to Charleston, where it materially aids in smelting the mill concentrations.

TOMBSTONE DISTRICT.

GIRARD.—An important strike has been made. A ledge fully fifteen feet in width and assaying one hundred ounces per ton in silver has been found. A large force of men will no doubt be put to work. This is the most important strike made in the camp for some months. According to the Tombstone *Epitaph*, the Girard mill and mine were recently sold under judgment by the sheriff, to Mr. W. J. Cheyney, Secretary of the Tombstone Mining and Milling Company, for $60,000. This includes the judgment against the property held by Judge G. G. Berry, under which the former sale for $49,968.40 was made. The recent strike will probably induce its redemption by them.

GRAHAM COUNTY.

DETROIT.—The Detroit mine, of the Longfellow group, is showing up well. In the forty-two foot shaft, a fine body of carbonate ore has been encountered. A drift of thirty-six feet was run, all in ore which at least will average twenty-five per cent in copper. It is the intention of the company to prospect this property thoroughly.

GREENLEE DISTRICT.

The gold mines in this new district, the discovery of which we mentioned some time ago, are reported to be opening up with very satisfactory results. A test made from the ores of these mines at Denver, Colo., gave an average return of $27 gold.

PIMA COUNTY.

ESPERANZA.—The mill is ready to start up on ore from the mine. At present a lack of water prevents its running.

ORION.—The mill has been running on ore from the Montana mine for some time, with satisfactory results.

PEERLESS.—The company continues to extract ore which is freighted to Tucson, and stored, with a view of having it reduced there, though some shipments of second and third-class ore from the mines of this company have been made to Benson and the Argo works at Denver. The shipping ore from these mines will continue to Tucson for reduction, as soon as the smelters are ready to begin operation. The company has resolved to sink a deep shaft on the Peer mine. In the mean time, the extraction of ore will continue from the surface as heretofore, which will pay largely over and above the cost of taking out and freighting to Tucson.

CALIFORNIA.

NEVADA COUNTY.

SOUTH YUBA WATER AND MINING COMPANY.—During the month of October, the Nevada mine, belonging to this company, was not worked because of short water. Work has been resumed, and the usual amount of bullion will be produced in November.

PLUMAS COUNTY—GREENVILLE DISTRICT.

SOUTHERN EUREKA.—A strike is reported. When the mill was last run, the best ore ever found in the mine was taken from the bottom of the tunnel. Another tunnel has recently been run to reach the same chimney at a greater depth. This tunnel has now reached the ledge, and a drift has been pushed into the chimney about forty feet, and at a depth of about 168 feet below the other tunnel. The mill will be put in order and started up again without delay. This last tunnel has added very much to the supply of water.

CANADA.

PROVINCE OF NOVA SCOTIA.

OXFORD.—The property adjoining this mine, recently purchased by Adams & De Camp, of New York, for $20,000, has been sold by them to the Oxford Company at the same price. The new lead on it is developing into a very rich vein, in some places being two feet wide and rich in gold. A large force of men is now at work on the property, and a considerable increase in the output of bullion will soon begin.

COLORADO.

ARAPAHOE COUNTY.

At a depth of 350 feet, the Union Addition Artesian Well Company, of North Denver, has struck oil.

CLEAR CREEK COUNTY.

The shipments for the month of October are reported as follows:

Boston & Colorado Works	230	tons.	$25,355
Silver Plume Sampling Works	160	"	11,000
Miners' Sampling Company	130	"	14,105
Morris & Noone	244	"	30,040
G. W. Hall & Co.	25	"	5,625
Total	789	"	$86,125

Charles H. Morris, of the Rocky Mountain mill, and W. S. Duncan, of the Pelican mill, Georgetown, have opened a public ore-market in the latter mill, where ore of all grades, in quantities over one thousand pounds, will be crushed and sampled, a sample furnished to the owners of the ore, and one sent to each of the smelters, or to their resident agents at Georgetown, who will put in their bids, addressed to number of the mill lot, on Tuesdays and Fridays of every week, the smelters or agents bidding the highest prices taking the ore, after paying the owner the full amount bid, without any reduction. All small lots will be sent to the Rocky Mountain mill, Georgetown.

FREELAND.—A rich strike is reported to have been made in the main shaft of this mine, at a depth of over 900 feet.

NEW YORK & COLORADO MINING AND MILLING COMPANY.—The Big and Little Chief lodes are operated by this company. On the first-mentioned, there is a main tunnel run 300 feet, opening up a mineral vein from four to five feet wide, carrying quartz with iron pyrites and purple copper ore. The Little Chief has a 150-foot drift, showing from two to three feet of milling ore. There is also a shaft sunk on the vein some 35 feet deep. In the mill and mines, there are about 50 men at work. The mill is about 50 rods from the mines, and is connected by a tramway which runs to the upper floor. The capacity of the mill is 150 tons of ore per day.

RED ELEPHANT.—A new plant of machinery for the White mine and Schwarz shaft on Red Elephant Mountain has been put into position. The plant has a sixty horse-power boiler and a forty horse-power engine.

SUNNY SOUTH.—The mine has been shut down on account of the immense amount of water encountered. A new plant of machinery will be put on with pumps, when operations will be resumed.

VULCAN.—Eleven lessees, in addition to the owners, are working on this property. The Egan level has been driven 350 east of the Egan tunnel. Work at present is concentrated on the stope. A rise is gradually making to the upper shaft, which will be tapped in about 120 feet. The ore grade and output continue high and steady.

CUSTER COUNTY.

BULL-DOMINGO.—While cleaning out the 350-foot level, a vein of mineral at least eight feet thick was discovered. It is of a different character and far richer mineral than any ever before found in the mine.

GILPIN COUNTY.

KING.—The company has begun pumping operations. The water has been lowered below the 200-foot station, and the superintendent expects to have the water out soon, and the shaft in readiness for sinking shortly after.

LAKE COUNTY.

ARGENTINE.—The company, after an unsuccessful campaign of several months, finally decided to lease its properties, and half a dozen parties are now engaged in working different portions of the old Gallagher mine.

BELLE LODE.—Shipments are now made to the Arkansas Valley Smelting-Works of ore from this mine, which it is stated averages one hundred dollars per ton. The property is situated in Sowbelly Gulch, about three miles north of Sugar Loaf Mountain. The mineral was struck, so the report says, at twenty feet from the surface, and a twenty-foot body of ore has since been opened. The ore is similar to the product of the Little Frying Pan mines.

BUCKEYE.—This mine, situated on Fryer Hill, adjoining the Chrysolite and Little Chief mines, has struck a pocket of fine-looking ore. The mineral consists of black iron and galena. The property contains nearly 2000 feet of development-work, and this is the first ore ever encountered.

CARBONATE HILL.—The annual report presented at the recent meeting showed a total production for the year ended November 1st of $110,000. Out of this amount, the expenses at the mine consumed $40,000, and $70,000 were transmitted to the New York office. Six dividends of $10,000 each have been paid within a year past.

CUMMINGS & FINN.—Finn, Grant & Co. have begun to receive ore at the Cummings & Finn smelter. There are about 1200 tons of ore on the premises, purchased by the retiring firm, which the new company also receives.

EVENING STAR.—The Leadville *Herald* says that the ore resources of this mine are rapidly decreasing, and the future of the property, unless new ore-bodies are soon discovered, is not over-flattering. The present ore production of the mine is secured mainly in gleaning through the large stopes, from which hundreds of thousands of dollars' worth of ore have been extracted in the past. Naturally, such a source of supply is very unreliable, and can not be expected to hold out very long. The mine is also shipping some iron ore. At the upper shaft, which is to be sunk to a greater depth, stations are now making for relief tanks for the pumps, and other provisions for an early resumption of work in this direction. The large pumping-engine and pump rig on the surface are all complete, and work satisfactorily. Four or six weeks will witness the sinking of the shaft again in operation.

LEADVILLE CONSOLIDATED.—The most extensive and productive ore-bodies of the Carbonate mine are as follows: At the foot of the Crane shaft, which is situated about 100 feet north of the engine-house. For some months past, this pocket has yielded twenty to thirty tons a month of one hundred dollar ore. Another profitable ore-body is situated in the extreme northern end of the Carbonate claim. The largest ore-body in the mine is located near the junction of the south incline and No. 10 level. A large area has here been stoped out and fine ore is left standing on all sides. A number of smaller ore-bodies are to be seen in various other portions of the mine, and a great deal of available ground is still left for prospecting.

LITTLE CHIEF.—No. 9 shaft, located on the southern end of the Little Chief claim, has been reopened and sinking has commenced. The shaft has a depth of

Digitized by Google

136 feet, and is still in porphyry. The shaft is on a piece of unexplored territory.

MORNING STAR.—The excellent results that followed the sinking of the McHarg shaft, and the great success attending exploration-work from this shaft, have greatly enhanced the prospects as well as the present value of this property. The shaft has quite recently been connected, by a working level, with the head of the Waterloo incline, and all the ore formerly hoisted through the Waterloo incline and shaft is now brought up through the McHarg shaft; from 35 to 40 tons are hoisted a day from this shaft. The change is a very desirable one, as it expedites the extraction of ore, and has allowed the company to get along with about fifteen less men than heretofore, and yet do the same amount of work.

PROSPECT LODE.—The latest discovery of mineral on Carbonate Hill is reported in the Prospect incline, the property adjoining the Leadville Consolidated mines on the south. Several years ago, an incline was sunk on this claim to a depth of five hundred feet or over, and yearly since then the required assessment-work has been done. During all this time, however, not a pound of ore was obtained. The property has recently been leased. In examining the incline for a suitable point to begin work, the first stroke of a pick disclosed a streak of lead carbonates. Several assays have so far been made, returning respectively 32 and 40 per cent of lead, and 17 and 30 ounces to the ton. The mineral is a gray sand and galena, and was found in the contact.

TERRIBLE VS. ARGENTINE.—In the United States Court at Denver, the Terrible Mining Company against the Argentine Mining Company, in a conflict between the Adlaide and Camp Bird mines, was tried before a jury, and a verdict secured in favor of the Adlaide. The defendants have given notice of their intention to move for a new trial.

OURAY COUNTY.

It is reported that Mr. William Weston has just made a sale, to English capitalists, of the Agnes and Declaration mines in Imogene Basin, price $50,000.

CIMARRON.—The men who were members of the Miners' Union and not getting three dollars per day and their board recently struck; in consequence, the mine has been closed down.

PARK COUNTY.

CHICAGO SAMPLING AND CONCENTRATING COMPANY.—This company has purchased the Park County Sampling and Concentrating Works, located at London Junction, and having repaired the same, is now prepared to purchase good concentrating ores for cash.

PITKIN COUNTY.

It is estimated that there are nearly 1000 tons of ore at the smelter at Aspen. The average daily receipt is about 20 tons. The ore-house is full to the top, and new bins are building constantly to accommodate the ore coming in. It is now thought that, as soon as coke can be made and brought up from the Wheeler collieries on Four Mile, the smelter will blow in.

DAKOTA.

It is stated that New York capitalists who are interested in certain Rapid Creek properties will soon begin the work of development on them, and erect reduction-works.

CALEDONIA.—Work has stopped at the mine and mill for some unknown reason. An assessment of ten cents a share has just been levied.

FATHER DE SMET.—The superintendent reports, October 27th: At the mine, work is going on well, and every thing is in good shape for working economically. Golden Gate south header continues to hold its own in good ore, and is gradually developing an extensive body of it. We have breasted out into it about eighteen feet, and there are no indications of a wall yet. East cross-cut, third level, has disappointed us in not finding a better quality of ore, but it may change for the better any day. It is looking more encouraging to-day. The mill is running very well, and giving no trouble. For week ended November 7th, he reports: Ore extracted from first level, 950 tons; second level, 600 tons; third level, 400 tons. Ore milled, 1950 tons. Golden Gate east cross-cut, third level, advanced eight feet.

MINNESOTA.—Negotiations for the sale of this mine are pending.

ORO FINO.—The shaft is down 75 feet, following the wall and disclosing a fine body of ore, assaying well in gold and a large percentage in silver.

ROCKERVILLE HYDRAULIC COMPANY.—Operations at these works have been discontinued for the winter.

STAND-BY.—Preparations for milling on an extensive scale are making, and it is expected that work will continue all winter.

IDAHO.

The Wood River *Times* states that the smelter at Bellevue will probably not be finished this year, and that it is doubtful if it is ever operated by the present management.

BALTIMORE.—This group has been sold for $30,000. The developments made show that the group is on the Elkhorn mineral belt. The work done on the Baltimore includes an incline which is down over 100 feet, and a drift about 75 feet long from the bottom of the incline. On the Victoria, which adjoins the Baltimore, there is a tunnel which is over 100 feet long, and shows an ore-vein from one foot to seven or eight feet wide. In the progress of work, about $10,000 worth of ore has been extracted, which is now on the dumps.

COLUMBIA & BEAVER.—The mill will probably close down for the winter at the end of this month. During its run of forty-five days, it has turned out $60,000 worth of bullion. Operations at the mines and mill, next summer, will be pushed vigorously, and the capacity of the leading plant of the mill will then be greatly increased.

PHILADELPHIA SMELTING COMPANY.—It is estimated that the production this season will amount to over seven million pounds of base bullion, worth about $1,300,000.

MAINE.

The silver vein on the land of E. L. French, South Exeter, is in a fair way to be developed. The property has been bonded by M. B. Spinney, W. H. Sweet, J. W. Kelly, and others of Bath, who are making arrangements to open it up and ascertain its extent and value.

DOUGLAS.—At the directors' meeting, reference to which was made in the last issue of the JOURNAL, Hon. F. M. Laughton, of Bangor, was chosen president. It has been decided to employ a practical mining engineer to examine and report as to the condition of the mine, before laying out plans for the coming winter.

STEWART.—Work on this mine, Blue Hill, is progressing satisfactorily. The northerly cross-cut is in 110 feet from the shaft, and the character of the ground is improving—the rock growing softer. It is calculated that at 140 feet the vein exposed by the open cut will be reached. The work of sinking the main shaft is going on continuously, and in the southerly cross-cut, which is in some thirty feet, an eight-foot vein of good copper ore has just been penetrated.

MARYLAND.

A bed of marl has recently been discovered near Cambridge. There are three strata. The first is of a rich brown color, thoroughly decomposed. The second is lead-colored. This stratum seems to have but lately decomposed, as there are still visible impressions of various sea-shells and bones. The jaw-bones of some very large animal have been discovered. The third stratum is of solid bone or rock, and, when powdered, closely resembles pure bone.

MICHIGAN.

The L'Anse & Houghton Railroad will be ready for business very soon. Both districts are to be congratulated on this important acquisition, especially those of the copper section, who have long since been inconvenienced by the lack of it.

The product during the month of October and total for the year of the mines mentioned has been as follows:

	October.	Total.
Calumet & Hecla	1,807	17,102
Quincy	351	2,677
Atlantic	166	1,607
Franklin	196	1,708
Allouez	100	1,004
Pewabic	48	631
Peninsula	61	483
Grand Portage	43	378
Hancock	37	386
Wolverine	40	289
Centennial		
Copper Falls	43	
Huron	70	181
Conglomerate		99

The amount for the Conglomerate is for the first four months, no stamping having been done since April 30th, on account of building the new mill.

CONGLOMERATE.—The stamp-mill is to be lighted by electricity. The last rail has been laid on the railroad from the mine to the mill, the piers at the canal entrance are completed, and there is now a sufficient depth of water to admit vessels fully loaded. It is expected that the mill, when in complete running order, will be capable of stamping 600 tons of rock daily.

DEER LAKE.—This company has joined with the Ropes Gold and Silver Company in exploring the property adjoining the Ropes land on the west. Good encouragement has been met with thus far. A fine quartz-vein has been discovered a few feet from surface where the first test-pitting was done. The Deer Lake Company owns other lands besides this that hold gold and silver-bearing veins.

EAST VULCAN.—Ore was struck in the new shaft twelve feet from the surface.

EMMET.—This company is just finishing the largest shaft-house in the mining region, and will have machinery to hoist 800 feet per minute, and electric signals and electric lights.

OLD CLIFF.—The recent operations on the north side of the range, in the Old Cliff property, seem from all reports to have a fair prospect of resulting in the development of a very valuable copper mine. The work was prompted by discoveries made about a year ago by Mr. Martin Kirshwing, who subsequently called the attention of Mr. D. D. Brockway to them. Openings have been made along the course of the vein, and during the past season the mine has been opened at nine different points. The result has been so encouraging as to induce the owner to sink three shafts and develop the vein in a thorough and systematic manner.

PAINT RIVER IRON COMPANY.—The company is considering the erection of a furnace at Crystal Falls for the treatment of a portion of the product of the Paint River and Mastodon mines, the property of the company.

MONTANA.

LEWIS & CLARKE COUNTY.

DRUM LUMMON.—Three bars of gold and silver bullion, valued at $10,000, were recently produced. The output of this mine will be large as soon as the new mill is up and ready for work. A force of men has begun to prepare for its erection, and it is hoped that it will be completed by next summer. Meanwhile, the little five-stamp mill will continue to run.

HELENA MINING AND REDUCTION COMPANY.—About complet.d at these works, are a 150-ton concentrator, and another 80-ton concentrator, and two 20-ton furnaces, and a 20-ton mill. This company will mine at least 250 tons per day, of the value of $40 per ton. The bulk of this will be concentrated and shipped.

SILVER BOW COUNTY.

ALICE.—The amalgamations for the past month averaged 89·55 per cent, and the chlorinations 84·02 per cent.

COLUSA.—The ore taken from the drift of the old discovery-shaft showed that the first-class ore ran 63·9 per cent copper and the second class 36·8 per cent.

MOULTON.—The main object at present is to get the mine in good working shape and to open new stoping ground. In order to accomplish this result, the mill is kept partly supplied for a few weeks with custom ore, for the treatment of which, however, the company realizes a good profit.

WASHOE.—An important strike has been made.

NEVADA.

ESMERALDA COUNTY.

WESTERN BELLE.—This company has been incorporated, with a capital stock of $5,000,000, divided into 100,000 shares. It is said that the entire amount of the capital stock has been subscribed by five gentlemen, John Neat, of San Francisco, subscribing $4,980,000 and the four other gentlemen $5000 each. The principal place of business will be in San Francisco, and the company is formed for the purposes of mining and milling in all its branches in Columbia Mining District, and elsewhere in this State.

EUREKA COUNTY.

A special meeting of the Eureka Miners' Union was recently held in Eureka, for the purpose, it is supposed, of taking steps to close down certain mines in which non-union men are working for less than $4 per day; or to require the men to join the Union and work for Union prices.

EUREKA TUNNEL.—The troubles of this company, reference to which has been made at various times in the JOURNAL, continue. The Eureka *Sentinel* states that all the mining claims belonging to the company were sold at sheriff's sale October 27th, in order to satisfy the judgment of the White Pine County Bank. The entire property was bought in by R. Sadler for the sum of $12,000, this amount being necessary to pay off the preferred claims which had been filed with the sheriff, and the bank judgment. Prior to the sale, arrangements had been made with the miners by a syndicate to take up all the preferred claims at 93 cents on the dollar, cash, and all the preferred claims have been paid off at this rate. The personal property of the company has not yet been sold, it being under attachment sued out of the Justice's Court by P. N. Hansen. As the matter now stands, the property belongs to Messrs. Sadler, Capron, Muller, and Pardy. F. W. Clute has a judgment against the company for $36,000, and it is quite probable that he will redeem the property from the syndicate in order to save himself. From the present outlook, it will be some time before work can be resumed in the mine.

RICHMOND.—Th mine is partially closed down. The reason for this act on the part of the management, says the Eureka *Leader*, is a scarcity of ore on the upper levels and too much water on the lower levels. The machinery is closed down for the present, but will be started up as often as the tributers have ore to hoist.

NYE COUNTY.

BELMONT.—Stopes in the south tunnel are showing well. The ore extracted will mill from $150 to $200 per ton. The stopes in Laity ground are producing first-class ore in liberal quantity. The level going south shows the ledge to be 10

Digitized by Google

feet in width. The mill is doing good work. Chlorinations are high, averaging so far 92 per cent

WHITE PINE COUNTY.

STAR MINING COMPANY.—The case of Wells, Fargo & Co. *vs.* this company, of Cherry Creek, will come up in the Supreme Court of Carson shortly. This is said to be an important case, and the decision of the court will be of interest to laborers throughout the State, as it involves the constitutionality of the lien law in Nevada. It appears that Wells, Fargo & Co. advanced money to the Star Mill Mining Company, for which the latter gave a mortgage on the property. At the Star mill, several men were employed who had not received their wages for some time. These men, growing impatient, filed liens against the mill. Wells, Fargo & Co., however, say that their mortgage is prior to the liens, and bring suit against the mill to recover the amount of the mortgage.

SUNDOWN.—This mine, which adjoins the Black Jack mine, at Diamond, has been bonded to J. C. Clark for the sum of $20,000. It is the intention to commence work in the mine at once.

NEW JERSEY.

DICKERSON.—The sinking of the shaft at this iron mine is well under way. It is now a little over 100 feet deep, but will be sunk to a depth of 700 feet. This shaft is sinking to strike the vein at the foot of the slope, and when completed will be the outlet for hoisting the ore, which now has to be conveyed a long distance underground and up a long slope. The shaft is 8 by 16 feet, and will occupy some two years in sinking. There is a hoisting-engine and an air-compressor in position, at present; but they will be replaced by larger and more powerful ones when the ore is to be hoisted. Five large boilers have been set, which are to supply the steam for the present and also for permanent use when the shaft is completed.

UTAH.

BEAVER COUNTY.

HORN-SILVER.—Major Goodspeed has recently visited this mine, and has made some interesting measurements. In an interview with a reporter of the Salt Lake *Tribune*, he states that he found the mine worked out down to the third level, or to a depth of 150 feet, and some of the ore between the third and fourth levels stoped out. Hence he confined his measurements to the great body of ore, as yet untouched, lying between the fourth and seventh levels, and took no account or approximation of the ore below the seventh level, which is opened by a shaft 54 feet deep. By actual measurement, he found the average width of the ore-body between the fourth and sixth levels to be 70 feet, and the average length 150 feet, by 200 feet in depth, containing 2,100,000 cubic feet of ore. The seventh level exposes in length 240 feet of ore. From this level, the cross-cuts, none of which has struck either wall, show an average width of 70 feet by 100 feet in depth, aggregating 1,680,000 cubic feet of ore; or, allowing 10 cubic feet per ton, 168,000 tons. Between the sixth and seventh levels, the ore is said to be richer in grade. Up to the present time, the Horn-Silver has put out 150,000 tons of ore, besides buying into the Utah Southern Railroad and putting up the smelter.

JUAB COUNTY.

MAMMOTH.—A report from Salt Lake City states that the Earl of Onslow, who arrived there recently, has left for Tintic on a special train to inspect the Mammoth mine, being interested with the English company which two years ago began negotiations for it, but the negotiations for which have lagged till the whole affair is in an inextricable muddle. The debts are heavy. People are in hopes that the visit may result in something decisive.

SUMMIT COUNTY.

ONTARIO.—The drain tunnel in this mine is progressing.

WYOMING.

Articles of incorporation have been filed at Cheyenne for the Black Hills & Montana Railroad Company, with a capital of $10,000,000, divided into 100,000 shares. The incorporators are F. E. Warren, A. H. Swan, M. E. Post, W. C. Irvine, and C. E. Anthony. According to the articles of incorporation, the company has the privilege of operating a railroad in Wyoming, Montana, Dakota, and other territories.

PATENTS GRANTED BY THE UNITED STATES PATENT-OFFICE.

GRANTED OCTOBER 2D, 1883.

285,786. Purifying Iron with Carbonic-Acid Gas. John F. Bennett. Pittsburg, Pa.
285,828. Fuel-Magazine for Steam-Generators. George Mehring, Chicago, Ill.
285,860. Metallurgic Furnace. Edwin D. Wassell, Pittsburg, Pa.
285,861. Cutter for Revolving Puddling-Furnaces. Samuel T. Wellman, Cleveland, O.
285,883. Friction-Compressor for Dredging-Machines, etc. Asahel H. Fisher, Philadelphia, Pa., Assignor of one half to William C. Turner, same place.
285,895. Alloying Iridium. John Holland, Cincinnati, O., Assignor to the American Iridium Company, same place.
285,940. Friction-Clutch. Richard Wels, Dessau, Germany.
285,945. Method of and Apparatus for the Treatment of Spoil-Heaps of Collieries. Lawrence H. Armour, Gateshead-on-Tyne, County of Durham, England.
285,952. Apparatus for Loading Coal. William G. Barnard, Bellaire, O.
285,970. Ore-Concentrating Table. R Neilson Clark and Norris H. Cone, Leadville, Colo.
286,025. Process of Obtaining Precious Metals from Refractory Ores. George T. Lewis, Philadelphia, Pa.
286,028. Sheet-Metal Pulley and Drum. Norman Macbeth, Bolton-le-Moors, County of Lancaster, England.
286,050. Concentrator. George A. Metcalf, Malden, Mass.
286,052. Dumping-Wagon. Charles Miller, Auburn, N. Y.
286,067. Process of Producing Ingot Iron and Steel. Jacob Reese, Alleghany, Pa.
286,074. Utilizing the Exhaust of Steam-Pumps. Henry W. Robie, Portsmouth, and William H. Lyons, Berkley, Va.
286,083. Grate-Bar. Charles Smith and Joseph Hutchinson, Chicago, Ill.
286,102. Rotary Steam-Engine. Augustus B. Wood, Fountain Hill, Ark.
286,104. Process of Treating Iron. Brock Woodruff, Albert Lea, Minn.
286,105. Steam-Engine for Mining Purposes. Bernhard Yoch, St. Louis, Mo.
286,110. Metallurgical Furnace. Simeon Bissell, Pittsburg, Pa., Assignor to Thomas Bakewell, Trustee.
286,117. Composition Paint for Metallic Surfaces. Henry R. Clothier, John Grogan, and John McMullen, Philadelphia, Pa.
286,119. Hod-Elevator. Samuel Dale, Boonesborough, Iowa.

RE-ISSUE.

10,389. Dumping-Platform. John T. Savage and John Love, Rockford, Ill.

GRANTED OCTOBER 9TH.

286,200. Antimony-Furnace. Arthur Hudson, Newton, Mass.
286,208. Process of and Apparatus for Reducing Zinc Ores. Leon Letrange, Paris, France.
286,223. Rock-Breaker. Lazarus Radovich, San Francisco, Cal.
286,286. Gas-Consuming Furnace. George Farr, Cincinnati, O., Assignor of one half to James Russell Whittemore and Myron Spiekerman, both of same place.
286,290. Pulverizing-Machine. Ryerson D. Gates, Chicago, Ill.
286,294. Ratchet-Drill. John A. Haase, Philadelphia, Pa.
286,320. Process of Converting Cast-Iron into Fibrous Wrought-Iron. Jacob Reese, Pittsburg, Pa.
286,342. Ore-Concentrator. William E. Stirk, Leadville, Colo., Assignor to A. P. Brayton, San Francisco, Cal.
286,364. Mining-Machine. Benhard Yoch, St. Louis, Mo.
286,466. Machine for Dressing Rollers for Grinding-Mills. Fred Messer, Beloit, Wis.
286,520. Clay-Pulverizer. William Andrus, Keokuk, Iowa.
286,549. Ventilating-Door for Mines. Casper P. Moyer, Woodville, Pa.

GRANTED OCTOBER 16TH.

286,720. Apparatus for Grinding White Lead and other Materials. John C. Martin, Richmond, County of Surrey, England.
286,721. Apparatus for Drying White Lead. John C. Martin, Richmond, County of Surrey, England.
286,723. Ore-Crusher. Frederick H. McDowell, New York City.
286,728. Brick-Kiln. Clark D. Page, Rochester, N. Y.
286,729. Brick-Kiln. Clark D. Page, Rochester, N. Y., Assignor of one half to Andrew Albright.
286,751. Hydraulic Air-Compressor. Hiram Webster, East Aurora, N. Y.
286,754. Art of Making Metallic Wheels. Charles O. Wilder, Chicago, Ill., Assignor to the Northwestern Steele Wheel Company, same place.
286,777. Smelting-Furnace. Edward Cartwright, Wilber, Neb., Assignor of two thirds to William H. Mann and John S. Edwards, same place.
286,791. Amalgamator. George Dean, St. Louis, Mo.
286,815. Miner's Pick. Samuel Herron, Coalton, Ky.
286,822. Combined Roasting and Smelting Furnace. Ezekiel Holman, Sandy, Utah.
286,825. Soft-Metal Casting Apparatus. Robert J. Howdon, Cincinnati, O., Assignor of one half to the Cincinnati Coffin Company, same place.
286,837. Rock and Earth Boring Apparatus. Theodore Lindell, Clarksville, Mo., Assignor of one half to Per Swainson, same place.
286,854. Device for Promoting Combustion in Boiler-Furnaces. Isaac W. Seaverns, Jr., Chicago, Ill.
286,887. Furnace. Jacob S. Williams, St Louis, Mo.
286,892. Brick-Machine. William Andrus, Keokuk, Iowa.
286,904. Manufacture of Metal. George H. Chinnock, Brooklyn, N. Y., Assignor to himself, Albert Sichel, and James Lemon.
286,986. Pick. William A. Wright, Centerton, N. J., Assignor of two thirds to A. J. Lamborn, Philadelphia, Pa.

GRANTED OCTOBER 23D.

287,004. Inlet-Valve for Air-Compressors. George R. Cullingworth, New York City.
287,005. Outlet-Valve for Air-Compressors. George R Cullingworth, New York City.
287,006. Journal-Box. George R. Cullingworth, New York City.
287,007. Inlet-Valve for Air-Compressors. George R. Cullingworth and Charles W. Potter, New York City, Assignors to the Sergeant & Cullingworth Company, same place.
287,032. Coal-Mining Machine. Samuel C. Lechner, Columbus, O.
287,038. Cleaner for Steam-Boilers. Arthur Lowcock, Shrewsbury, Shropshire, and John Taylor, Salford, County of Lancaster, England; said Taylor Assignor to said Lowcock
287,053. Pump. Jay W. Powers, Winnetka, Ill., Assignor of one half to Morris J. Moth, same place.
287,054. Process of and Plant for Producing Cast-Iron High in Carbon and with a Predetermined Percentage of Silicon. Jacob Reese, Pittsburg, Pa.
287,069. Steam-Pump Regulator. Jacob Wagner, Pickering, Mo.
287,074. Apparatus for Tempering and Preparing Clay for Making Brick. Walter W. Winn, Troy, N. Y.
287,101. Safety-Governor for Air-Compressors. George R. Cullingworth, New York City.
287,102. Rock-Drill Support. George R. Cullingworth, New York City.
287,103. Tripod for Rock-Drills. George R. Cullingworth, New York City.
287,104. Air-Compressor. George R. Cullingworth, New York City.
287,105. Pressure-Regulator for Air-Compressors. George R. Cullingworth and Charles W. Potter, New York City, Assignors to the Sergeant & Cullingworth Company, same place.
287,117. Process of Preparing Powdered or Granulated Ores for Furnaces. James J. Fronheiser, Johnstown, Pa.
287,131. Safety-Valve. Albert H. Jarecki, Erie, Pa.
287,139. Elevator-Bucket. Robert B. Little, Providence, R. I.
287,140. Coal Elevator and Conveyer. Robert B. Little, Providence, R. I.
287,161. Coal Sieve. John G. W. Putnam, Saratoga Springs, N. Y.
287,167. Safety-Valve. George W. Richardson, Boston, Mass., Assignor to the Consolidated Safety-Valve Company, Hartford, Conn.
287,173. Ore-Concentrator. Charles C. Rueger, San Francisco, Cal.
287,188. Connecting-Rod for Rock-Drills. Charles A. Sterling, New York City.
287,195. Ore-Separator and Amalgamator. Horace P. Tobey, Wareham, and George B. Thayer, Boston, Mass., Assignors to the Golden Gate Concentrator Company, Augusta, Me.
287,204. Blast-Furnace. Peter L. Weimer, Lebanon, Pa.
287,209. Drilling-Machine. Edward J. Worcester, Worcester, Mass.
287,235. Manufacture of Steel. William W. Chipman, Brooklyn, Assignor of two thirds to William Courtenay and Joseph C. Tiffany, both of New York City.
287,252. Double-Acting Steam-Pump. Evan Davies, Cleveland, O.
287,256. Combined Ore-Grinder and Amalgamator. Peter Eddy, Nevada City, Cal., Assignor of one half to James G. Hartwell, same place.
287,262. Friction-Brake for Elevating Devices. John A. Evarts, Meriden, Conn., Assignor to the Bradley & Hubbard Manufacturing Company, same place.
287,273. Apparatus for Treating Molten Iron. Robert H. Gordon, Reading, Pa.
287,325. Water-Pump Attachment for Air-Compressors. Charles W. Potter, New York City, Assignor to the Sergeant & Cullingworth Company, same place.
287,332. Coke-Oven. Louis Semet, Brussels, Belgium.
287,358. Hydraulic Air-Compressor. William A. Babcock, South Coventry, Conn., Assignor to Bishop & Babcock, Cleveland, O.
287,396. Dry Ore Concentrator. John George Vollmer, Austin, Tex.

REISSUE.

10,395. Process of Analyzing Pig-Iron from Blast-Furnaces. Samuel A. Ford, Pittsburg, Pa.

GRANTED OCTOBER 30TH.

287,403. Turbine Water-Wheel. Henry R. Austin, Norwood, N. Y.
287,431. Amalgamating Apparatus. Ellick H. Gollings, Lewiston, Idaho, Assignor to himself and Charles H. Smith, Chicago, Ill.
287,432. Brick-Kiln. Francis L. Hall, Oneida, N. Y.
287,433. Gas and Coke-Kiln. Hayden H. Hall, New Hamburg, N. Y.
287,436. Coal-Mining Machine. William Hilton, Barton, O.
287,508. Centrifugal Pump. Nicholas Didiot, Bakersfield, Cal.
287,546. Ore Concentrator and Amalgamator. Frederick M. Johnson, Gardiner, Oregon.
287,579. Combined Boiler and Steam Vacuum-Pump. Carrall I. Riker, Brooklyn, N. Y.
287,633. Brick-Kiln. George F. Cotton, Bushnell, Ill.
287,646. Apparatus for Casting Copper. William F. Durfee, Bridgeport, Conn., and Thomas Egleston, New York City.
287,650. Dumping-Car. William Fallon, Newburg, N. Y.
287,653. Machine for Pulverizing Ores, etc. Arthur L. Fish, San Francisco, Cal.
287,658. Pulverizing-Machine. Ryerson D. Gates, Chicago, Ill.
287,663. Dumping-Car. James T. Godwin, Norfolk, Va., Assignor of one half to Albert L. Woodworth, same place.
287,679. Apparatus for Preparing and Treating Peat for Fuel or other Purposes. J. Burrows Hyde, New York City.
287,687. Manufacture of Bessemer Metal. William R. Jones, Braddock, Pa.
287,699. Manufacture of Brick. Frederick W. Meeker, New York City, Assignor to the Fire-Proof Building Company of New Jersey.
287,728. Tunneling-Machine. Maier Rothschild, Shamokin, Pa.
287,737. Process of Treating Sulphides. Carl A. Stetefeldt, New York City.
287,754. Air-Injector for Furnaces. James W. Bonta, Philadelphia, Pa., Assignor to the Giant Air-Injector Manufacturing Company (Limited), same place.
287,784. Metal-Crimping Tool. Richard Whitaker, New Brunswick, N. J., Assignor to Alvin L. Fisher, same place.
287,785. Can for Holding Blasting-Cartridges. Chauncey C. White, Peckville, Pa.

REISSUE.

10,399. Furnace and the Art of Working the same. James Henderson, Bellefonte, Pa.

Digitized by Google

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Nov. 16.

There was a slightly improved feeling in the mining market this week, and the dealings were more generally confined to the better class of stocks. The chief stock of interest dealt in was Horn-Silver, which at one time was quite strong. It reacted, however, and closed weak to-day. Iron Silver was another feature of interest, and was remarkable for its weakness. It is the impression that it is manipulated to create a "short" interest and then to "bull" the stock. Chrysolite shows some strength under moderate dealings. Some of the fancies were largely dealt in, but show no material change in price. Below will be found a complete summary of the market. The total number of shares sold aggregates 121,565, as against 97,665 last week.

The Comstock shares were almost neglected, and were generally weak. California was quiet at 25c. Consolidated Virginia was weak, under a small business, selling from 47@38@43c. Sierra Nevada was also weak at $3.50@$3.15 with small transactions. Mexican sold at $2.50, and Hale & Norcross at $1.60. Sutro Tunnel was very quiet at steady prices, selling at 15c.

The Leadville stocks were moderately dealt in at steady prices. Amie was quiet and steady, selling from 12@14c. Chrysolite was strong, with a fair business, selling from $1.25@$1.35@$1.30. Dunkin sold from 26@25c. Breece was quiet and steady at 17c. Iron Silver was weak, with a moderate business, selling from $2.90@$2.25@$2.35. Leadville was quiet and steady at 46@49c. Little Chief sold from 56@55c., with a small business. Little Pittsburg was steady under a small business, selling from 50@57c. Climax sold at 6c.

The Bodie stocks were very quiet and were steady. Bodie Consolidated sold from 45@40c., with a small business. Standard was quiet and steady at $6.25@$6.38. Bulwer was steady at 50@45c., with small ransactions.

The Tuscarora stocks were very quiet. Grand Prize was weak, under a small business, selling from 50@42c. Argenta sold at 20c. Elko Consolidated was quiet and steady, selling from 18@19c.

In the miscellaneous list, Bassick was irregular, under a small business, selling from $8.38@$9@$8.50. Eureka Consolidated was weak at $3.90. Green Mountain was strong, selling from 85c.@$1, buyer's option; the business was small. Homestake was quite weak, selling from $10@$8@$8.25. Horn-Silver was quite strong at one time, but suffered a decline toward the close; it sold from $5.50@$6.75@$6. Robinson Consolidated was weak, with a small business, selling from 45@39@40c. Sierra Grande declined from 98@94c., under small transactions. Silver King was quiet and steady at $7. Castle Creek sold from $1.20@$1.10: the transactions were small.

Barcelona was quite active at weak prices; it sold from 21@23@22c. Caledonia was a little weak at 30@25c. Decatur was very active at steady prices, selling from 4@5c. Eastern Oregon was quiet and steady, selling from 42@43c. Harlem was moderately dealt in at steady prices; it sold from 96 98c. La Crosse sold from 8@12@9c., with a small business. Sonora Consolidated was weak during the early part of the week, but was stronger at the close; it sold from 25@22@27@26c., with a very active business.

MEETINGS.

The Consolidated Batopilas Silver Mining Company, No. 82 Broadway, New York City. Annual meeting of stockholders and election of trustees November 26th, at twelve o'clock M.

The Hibernia Silver Mining Company, office of Messrs. Lexow & Haldane, attorneys, No. 46 Exchange Place, Room 48, New York City. A special meeting of stockholders for the purpose of voting on the question of returning the contributions, December 1st, at three o'clock P.M.

The St. Joseph Lead Company, No. 152 Broadway, New York City. A special meeting of stockholders for the purpose of considering the question of increasing the capital stock from $1,000,000 to $1,100,000, December 4th, at one o'clock P.M.

DIVIDENDS.

The Bassick Mining Company, of Colorado, has declared a dividend of one dollar per share, payable on and after November 27th.

The Holyoke Mining Company, of Idaho, has declared a dividend (No. 14) of two per cent on the capital stock, payable November 19th.

The Homestake Gold Mining Company, of Dakota, has declared its 63d dividend of $25,000, for the month of October, payable at the office of the transfer-agents, Lounsbery & Haggin, No. 15 Broad street, on the 24th inst. Transfers close on the 20th. Total of dividends to date, $2,262,500.

The Jocuistita Mining Company, of Mexico, has declared a quarterly dividend (No. 10) of $50,000, being fifty cents per share, payable November 30th.

The Mount Diablo Mining Company, of Nevada, has declared a dividend of twenty-five cents per share, paya ble November 26th.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway, report on the petroleum market for the week as follows:

A week ago Friday, oil opened at 110 and began a journey upward that has reached 119¼ this Friday noon, with scarcely a reaction.

For a month, extreme dullness prevailed in the oil market, and the public was but little interested in it. It now appears that a short interest had been created and that oil had gone into strong hands, who started this boom to make a market to sell on.

The price of refined oil has been daily advanced a fraction from 8½ cents to 9, and this in presence of the fact that there is almost no foreign demand and only the usual domestic trade. The charters for export this month so far show a daily average of less than 18,000 barrels, against about 46,000 in September and October.

It would appear that the Standard Oil Company is either the author of this advance in crude oil or is at least friendly to it. There is not much short interest in any of the markets except Pittsburg, but the market is undeniably strong. The public are not in yet. The professional leaders are nearly all bulls. The bull argument is, that the field is showing a decline in production. Cooper tract and Balltown are only about 3000 barrels per day below their maximum production, and there is nothing to show that consumption is in excess of production. The market suffered a strong decline this afternoon, and closed in a feverish and unsettled condition.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Nov. 10	$1.12⅝	$1.14	$1.12½	$1.13⅝	4,857,000
12	1.14¼	1.16	1.14¼	1.14¾	6,285,000
13	1.15⅛	1.15⅝	1.14⅝	1.15¼	3,927,000
14	1.15⅝	1.17⅞	1.15⅛	1.17⅛	5,505,000
15	1.18⅜	1.19	1.17¼	1.18⅛	6,809,000
16	1.18⅞	1.19¼	1.17⅛	1.17¼	9,307,000
Total sales					36,690,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, November 15.

The dealings in mining stocks the past week have been few and far between; and with a single exception, prices are unchanged. In copper stocks, Calumet & Hecla is steady at $240, with sale of a single share to-day at $239, closing $238 bid, $240 asked. Franklin sold at $11⅛, same as last week—only one transaction for the week. Quincy is duller than ever; only 9 shares changed hands the past week at $52. Pewabic is exceptionally strong under orders to buy, and advanced from $31¼@$33¾; but the advance brings out but little stock. The owners of most of this stock paid high prices for it, and still have faith in the enterprise, and expect some day to get good returns for their patient waiting. The four stocks above named comprise all the dealings in coppers for the week, and show how little interest there is in this class of property. The outs do not want to get *in*, and the ins can not get *out*, and the result is dull business and few commissions for the brokers.

The silver stocks are gradually fading from the market. The transactions at the regular Brokers' Board are comparatively nothing, and at the Mining Exchange the same want of activity is noticed. Bonanza Development sold at $1.50—200 shares only. Catalpa, at 30c., at which the market is well supplied. Bowman Silver is floating about at 10@11c. Massachusetts & New Mexico is not wanted at any thing over 2c. per share. Sullivan seems to be the only stock in which there is any degree of activity. This stock is largely held by a few parties who are manipulating the market in hopes to be able to unload upon the public. The price has ruled quite steady at 90c.@$1 as the extreme limits. There have been some sales of Dunkin at 26@28c., but dealings are extremely limited.

3 P.M.—At the afternoon Board, Calumet & Hecla declined on sale of 41 shares to $238. Sullivan sold at $1⅛, and Catalpa at 30c. Allouez, $1½ asked. Atlantic, $12 asked. Bonanza, $1½ bid, $1⅝ asked. Calumet & Hecla, $238 asked. Catalpa, 30c. bid. Franklin, $11¼ bid. Huron, $1⅜ bid, $1¾ asked. Pewabic, $3½ bid, $4 asked. Quincy, $51 bid. Silver Islet, $3 bid, $4 asked. Sullivan, $⅛ bid, 95c. asked.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended November 16th, as compiled from various sources, amounted to $257,000, as against $885,396 reported for the previous week. The receipts from January 1st, 1883, to date are $10,155,448.

Digitized by Google

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended November 10th	$260,940
Corresponding week last year	52,500
Since January 1st, 1883	12,946,759
Corresponding period last year	44,614,221

Imports.

Week ended November 10th	$1,819,295
Corresponding week last year	299,538
Since January 1st, 1883	17,487,662
Corresponding period last year	5,028,169

Foreign Bank Statements.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at three per cent. During the week, the bank lost £2900 bullion, and the proportion of its reserve to its liabilities was decreased from 43⅜ to 42 11/16 per cent, against 38 13/16 per cent a year ago. The weekly statement of the Bank of France shows losses of 2,375,000 francs gold, and 2,525,000 francs silver.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14½ per cent, to arrive at actual value.

METALS.

NEW YORK, Friday Evening, Nov. 16.

Copper.—The condition of the market is, on the whole, healthy. From the West, come evidences of a forced restoration of the production, one of the leading concerns, it is stated, being unable to promptly meet its engagements for the delivery of raw material to refiners and exporters. It is certain that our refiners are getting less of blister mattes and ore than for some time past, so that the quantity of outside brands in our market is less. Lake is dull at nominally 15c., transactions being on a limited scale.

The English market has again shown symptoms of weakness, the last cable being £59 15s.@£60 for Chili Bars and £66@£66 10s. for Best Selected.

Tin.—There has been considerable excitement in this metal, the transactions at the Exchange amounting to 580 tons of tin, spot and futures, in the three last days, spot selling as low as 19½c. for Straits. London went down to £87, but has since recovered to £88 10s.

Messrs. James & Shakspeare, of London, have issued the following statistics of copper for England and France, including metal afloat:

	Oct. 1 to 31. Imports. Tons.	Deliveries. Tons.
Fine foreign, chiefly Australian	866	1,086
Chili { Bars	1,216	1,787
Chili { Ingots	385	308
Chili { In ores and regulus	22	274
American	946	824
Spanish precipitate and sundries	1,800	3,914
Totals, England	5,235	8,203
American	270	320
Chili bars, ingots, and Barilla, France	1,460	953
Sundries, France	25	25
Total, England and France	6,990	9,501

	Stocks. Oct. 31. Tons.	Sept. 30. Tons.
Fine foreign, chiefly Australian	3,680	3,900
Chili { Bars	24,574	25,155
Chili { Ingots	613	536
Chili { In ores and regulus	1,863	2,115
American	219	97
Spanish precipitates and sundries	2,224	4,338
Totals, England	33,173	36,141
American	290	340
Chili bars, ingots, and Barilla, France	2,429	1,922
Sundries, France	30	30
Total, England and France	35,922	38,433
Advised by mail and telegram: Chili	9,981	10,200
Australian	430	900
Stock and afloat, gross totals	46,333	49,533

	Jan. 1 to Oct. 31. 1883. Tons.	1882. Tons.	1881. Tons.
Imports	78,399	65,552	63,258
Deliveries	77,604	70,356	68,480

Messrs. James Lewis & Son, of Liverpool, estimate the total arrivals of copper from the United States in that port for the first nine months at about 7125 tons of fine copper.

The following are the Board of Trade returns, the most striking feature of which is the heavy increase in the quantity of Spanish precipitate:

Imports:	1883.	1882.
Ores, Chili	182	36
Cape	4,221	3,823
Other countries	6,730	6,502
	11,143	10,361
Regulus, Chili	2,463	2,977
Precipitate, etc	25,033	18,064
Bars, ingots, etc., Chili	16,508	14.904
Australia	7,928	7,242
Other countries	1,995	3,805
	11,983	12,125
Pyrites	77,053	69,478
Exports:		
Wrought and unwrought (English)	23,747	21,251
Yellow metal (English)	8,840	8,385
Brass (English)	2,551	2,484
Unwrought and part wrought (Foreign)	5,907	9,121
	44,045	41,241
Difference	33,008	28,237
Stocks of all kinds, in England, January 1st	32,623	35,306
Stocks of all kinds, in England, September 30th	36.141	31,030
Increase	3.518	
Decrease		3,676
Apparent home consumption of foreign copper	29,490	31,913
Produce of Cornish mines	1,793	1,826
British ores sold at Swansea	53	42
Apparent home consumption	31,336	33,781
Stocks of copper of all kinds in France were, January 1st	2,504	3,437
Stocks of copper of all kinds in France were, September 30th	2,292	2,965
Decrease	212	472
Import of copper of all kinds into France directly	15,815	11,588
Apparent French consumption (exclusive of import from England)	16,027	12,060
Apparent French consumption (including import of English copper)	20,837	17,078
Total English and French consumption of English copper and English export	91,408	87.082

Lead.—This metal has taken another plunge downward, sales having been made yesterday and to-day of from 400 to 500 tons of Common at 3·75c., while Refined is nominally 3·80c. The decline, which was not looked forward to until a later period, appears to have been precipitated by the eagerness of refiners. The situation is becoming grave, and unless relief is obtained in some manner, will hurt the mining interests. It is argued that to the mines it is a matter of indifference what lead fetches; "their profit comes from the silver." This may be true in a few isolated cases, but the great bulk of the lead ores are carriers of the silver in drier ores, whose value is dependent upon the supply of the former. Let it be cut off, and the smelting charges for the latter run up to a figure putting their profitable mining out of the question. The lead and silver mining interests can look for relief only in one quarter. The exorbitant rates of the railroads carrying bullion to the refiners from the smelters must come down. There is a good deal of mystery about these rates, and it is freely charged that some of the Western desilverizing works are unduly favored. Be this as it may, from $20 to $30 per ton is too high in bullion from Colorado smelting-works to desilverizing establishments in Missouri, Kansas, and Illinois, from which the refined lead can be sent East in some cases as low as $6 per ton.

Messrs. John Wahl & Co., of St. Louis, wire us as follows to-day:

Our market has declined slowly since our last report, there being no demand. Buyers were few, and make their own terms. Sales will not aggregate 400 tons at 3·65@3·70c. Hard Missouri is quoted at 3·60c.

Messrs. Everett & Post send us the following dispatch from Chicago to-day:

There being more sellers than buyers in the market, prices have weakened, and buyers who expect a further decline hold off, purchasing only for immediate requirements now. Sales for the week figure up to 800 tons, prices ranging from 3·60 down to 3·50c., closing nominally 3·50@3·55c.

Spelter.—Under the pressure of occasional forced sales, promptly picked up, spelter remains low, being quoted for Common Domestic 4⅝@4½c. Some Glendale, which is a favorite brand of brass-makers, has been placed at 4·95c., and a small lot of Silesian at a higher figure. The outlook for some of the smaller smelters in the Joplin District is not encouraging, the price of ore having been forced as high as $5 per ton.

Antimony remains unchanged.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Nov. 16.

Mr. Edward J. Shriver, Secretary of the Metal Exchange, has the following returns:

130 furnaces, all kinds; 75 in blast, 55 out of blast.

All grades.	Stocks. Oct. 1.	Stocks. Nov. 1.	Production. In Sept.	Production. In Oct.
Anthracite—25 in; 19 out	28,979	28,550	17,862	18,877
Bituminous—21 in; 21 out	31,461	31,927	19,967	26,538
Charcoal—28 in; 16 out	27,477	27,739	11,595	12,349
Grand total	87,917	88,216	49,424	57,764

American Pig.—The slight indications of an improvement noted in our last have been confirmed during the present week, although they have not gathered to any extent in strength. The fact remains that, on the whole, the season has been far behind the expectations of furnace-men. As indicating to what the long-continued policy on the part of consumers, of purchasing only from hand to mouth, has led, it may be stated that very prompt delivery is, in the majority of cases, insisted upon. This proves that the stock is almost entirely held by producers, and therefore will appear to be larger than the facts in the case really warrant. Transactions have been on a fair scale at unchanged prices, which we quote: Foundry No. 1, $20@$22.50; No. 2, $19@$20; and Gray Forge, $17.50@$18.50, all at tide-water. Bessemer pig is dull at $20@$20.50, and Spiegel is quiet at $30.50@31 for 20 per cent.

At the Exchange, the following transactions were reported during the week:

Saturday, 200 tons, January, $20; 200 tons, February, $20.12½. Thursday, 100 tons, January, $20.25; and to-day 100 tons, December, $20.25, and 200 tons, January, $20.50.

Scotch Pig.—The market is dull and depressed, and, in spite of the fact that arrivals are moderate, some of the iron goes into store.

We quote ex ship and to arrive: Coltness, $23; Langloan, $23@$23.25; Summerlee, $22.50@$23; Eglinton, $20@$21; Glengarnock, $21.75@$22; Dalmellington, $20@$21.

At the Exchange, the following cable quotations were received to-day: Coltness, 55s. 3d.; Langloan, 55s.; Summerlee, 54s. 6d.; Gartsherrie, 52s. 9d.; Glengarnock, at Ardrossan, 53s.; and Eglinton, at Ardrossan, 46s. 6d. Warrants at the Exchange to-day were 44s. 7d.

Rails.—It is reported that the aggregate of the sales East and West during the past week has been 140,000 tons, at $35 at Eastern mill and $37 laid down at Chicago. We have reason to believe that all but a small part of this total, 15,000 to 20,000 tons at the utmost, must be Western, because Eastern mills have taken few orders. The report has been circulated, but is positively denied, that one Eastern mill has sold rails at $34 at mill. We are in a position to state emphatically that such is not the case. An amusing item has been started in its rounds, and will probably during the next few weeks turn up with that obstinacy which absurd statements have, in which some misguided reporter has been led to compare the difference in the cost of fuel to the Edgar Thomson, the Lackawanna, and one Western mill. In a neat little table he shows what coke costs at the oven, and what the freight of that fuel is to the different works mentioned. It is unfortunate for him that the Lackawanna Company does not use coke in its blast-furnaces, except very rarely, under special circumstances.

Old Rails.—There has been a little more activity. We quote Tees $20.75@$21 for large lots.

Philadelphia. November 16.

Pig-Iron.—The past six days have developed an improving tendency in some kinds and qualities of forge iron, and at present writing there are a number of inquiries for large lots on hand, which makers and brokers think will result in heavy orders for delivery during the next sixty or ninety days. But these sales will depend upon the acceptance of lower prices than are at present named. In some cases, a difference of 25 or 50 cents per ton holds back large orders. Consumers seem to have realized the fact that the market has at last reached the lowest limits, and are prepared to buy, if their offers are accepted. Generally speaking, the better grades of iron are under inquiry, the poorer makes having been neglected for a few days, notwithstanding the fact that large lots have been offered at very low prices. Parties who were offering large lots of mill irons ten days ago at concessions are now asking 25 cents more, and expect to get it. Selling prices range from $17@$19; very little desirable iron has sold this week under $18, and several good-sized lots have sold a little above this figure. Between 20,000 and 30,000 tons will sell this week for delivery in from sixty to ninety days, if offers are accepted. Foundry irons do not enjoy any activity deserving of attention, and several large lots have been offered this week as low as $20 and $20.50. The strong companies are still holding at $21, but are ready to make terms when buyers talk business. There seems to be no urgent demand for foundry, although yards are very slack of material.

Muck Bars.—Sales aggregating from 700 to 800 tons of Muck Bars have been made at $33.25@$34. Some stocks are held at $34.50, and command that in small lots where good quality is essential.

Blooms.—To-day's quotations show a little improvement in some makes, prices for these being from 25 to 50 cents higher than last week, but there is no general improvement. A number of lots of anthracite irons were sold at $47@$48, and there are offers in hand at $46.50.

Manufactured Iron.—The situation in merchant bar is still unsatisfactory, as it has been reported for a number of weeks past. Agents of Western makers have been traveling through the East, hunting out large buyers, and endeavoring to overcome some of the obstacles which have prevented the placing of large orders in the West, namely, the trouble as to assortments and guarantee as to quality. The mills have a number of inquiries in hand, which will probably result in business at about 2c. In some cases, iron has sold from Western mills at 1·90c. delivered. Prices are generally downward, and only in cases where extreme concessions are offered, can large lots be bought. City mills sell at 2@2·10c., and stores report a retail business at 2·10@2·20c. Common iron in country mills has been ordered more freely for car-work. One establishment at Berwick, Pa., has received a contract for 1000 freight-cars. Contracts for 1000 coal-cars have also been placed. Other railroad orders, aggregating from 1000 to 1500 cars, have been placed in this State inside of thirty days. These order will bring common iron into request, but there is no difficulty in obtaining it at 1·75@1·80c.

Nails.—Consumers of nails have taken the hint, and are buying only for current requirements. The action of the Western makers on Wednesday was anticipated here, and demand is irregular, and need not be expected to improve much during the winter, for the double reason that building activity is falling off and buyers expect that the heavy capacity will lead to a depression of prices, in spite of the five weeks' suspension ordered in the West. The East will continue production. Selling prices are $2.80 @ $2.90, and further concessions are looked for.

Plate Iron.—To-day's quotations are 2·35c. for Boat Plate; 2·40@2·50c. for Plate; 3@3·25 for Shell; 4@4·25c. for Flange; and 5@5·25c. for Fire-Box. Brokers have received several inquiries for large lots of Plate, and it is probable that business will be steady up to the end of the year.

Structural Iron.—Several orders have been received during the past week, one of 450 tons, and several smaller ones. One order for 1100 tons for delivery in Northern Ohio is in abeyance for the present. Engineering work calling for from 12,000 to 15,000 tons is in sight, and orders will probably be placed before the close of the year. Quotations are 2·40c. for Angles; 2·75@3c. for Tees; and 3·50c. for Beams and Channels, with concessions on large lots.

Steel Rails.—The sudden drop in steel rails to $35, instead of increasing business, has had a contrary effect. The reason seems to be that a general reduction in wages is anticipated on the first of January, to what extent is not yet known, and railroad builders are not willing to order for winter or spring delivery until this is decided. No heavy business will be placed this year. A number of small orders are coming along, and are taken at $36@$37, and a good many are offered at $35, but are not taken.

Old Rails.—Brokers here have more than usual inquiry for old rails, foreign and domestic, but have had but little success in meeting buyers' requirements. There are no stocks, and buyers' offers are below asking prices. Nominal quotations are $23@$23.50 for Foreign; $24 for American; and $25 for Double Heads.

Scrap.—Scrap-iron is in dull demand at $24@$25 for Selected. Cargo, nominal at $22.50. Steel Rail Crop-Ends, $23.50 offered.

Pittsburg. November 16.

The fact that pig-iron stocks have been gradually declining led this week to a number of inquiries for large lots of forge iron and the closing of some large contracts for delivery during December. Business will probably continue of a hand-to-mouth character with most buyers. A few, however, will risk large purchases, especially as the concessions offered are from 25 to 50 cents per ton more than those offered two weeks ago. Gray Forge is $17@$17.50. Charcoal irons, $24 for Warm Blast and $27@$28 for Cold Blast. Bituminous irons, $17 for Gray Forge to $17.50 and $20@$21 for Bessemer. The heavy orders referred to were placed at $17. Muck Bars are weak at $32.50. Merchant Bar ranges from 1·75@1·90c. Prices are very unsatisfactory, but nothing better can be done, and makers are running along in the hope of a better state of things before long. The season for the pipe mills is nearly over, and inquiry is declining. Discounts, 70 to 75 per cent. Nails are in moderate demand at $2.60@$2.70. Sales of steel rails have been made this week at $36.50 in small lots. Old rails are quoted at $23.50@$24 for American. Holders are refusing to sell at less.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Nov. 16.

The recent cold weather has caused a little more inquiry, and to that extent the market is in better shape. It does good rather in a negative than in a positive way, by preventing further additions to the considerable quality of coal afloat and causing some reduction in it. On the whole, the market continues dull, and the managers of the coal companies are probably looking with a sigh of relief to the approach of the first of December, which will terminate the period of forbearance wisely exercised in behalf of one of their number which is making so gallant a fight for a return to prosperity. Prices remain practically where they were, with occasional concessions of sizes that may for a short time be particularly pressing upon one or the other producer. Even from Philadelphia, usually too confident, come tales of "shading."

Bituminous.

The temporary scarcity of cars has forced some of the Clearfield operators to enter the market. They have purchased Cumberland coal at current rates, but are now fully supplied. The steamer trade is slightly better, but otherwise the demand from other quarters is disappointing for this season of the year.

WE print elsewhere the conclusion of our abstract of M. E. CUMENGE'S report on the Rio Tinto mine, which we believe leaves no doubt as to the future of that great enterprise. It is destined to play an increasingly important part in the copper trade of the world. The preparations for an increase in the output are on a magnificent scale, and the improvements introduced in the metallurgical treatment of the ores dispel all hope that in the long run any falling off in the world's supplies of copper, from the residues of burning pyrites in acid works, will not be fully compensated by an increased make on the spot, without reference to the revenue derived from the sulphur.

SCIENCE and the arts have lost in Sir CHARLES WILLIAM SIEMENS, who died suddenly of rupture of the heart, one of their leading workers. Dr. SIEMENS was one of the very few who have been able to make original contributions to science while engaged as leaders of progress in conducting large business enterprises in more than one branch of technology. As an inventor, a metallurgist, an engineer, and an electrician, his achievements are numerous and varied. One of eight sons of a family in moderate circumstances, he was born at Leuthe, Hanover, and after a course of studies at a polytechnic school and a university, he began work at the Stolberg engine-shops in 1842, at the age of nineteen. A year later, he for the first time visited England, which was to become his future home. He brought forward a series of inventions, in some of which he had the co-operation of his brother WERNER, and it was not until 1847 that he turned his attention to the study of the dynamical theory of heat, which ten years later led to the development of the regenerative system of firing with which his name and that of his brother FREDERICK are so closely associated. A little later, he took up the manufacture of iron directly from the ore, a process which has not, however, fulfilled the expectations of himself and his friends. In 1848, he turned his attention to electric and telegraph engineering, in which he was highly successful. England, his adopted country, delighted in showering honors upon him, while his brief sojourn in this country years ago won for him many friends.

IN a recent issue, we printed an interesting letter from Mr. W. W. SCRANTON, President of the Scranton Steel-Works, on the working of the Gjers soaking-pit at that establishment. Mr. JOHN GJERS, of Middlesborough, quotes it in a letter printed in a number of English technical journals, in which he gives some data on the rapid spread of the process in Europe. In Great Britain, the Darlington Steel Company, which was, we believe, among the first to take up the process, has rolled 60,000 tons of ingots into blooms from the pits. The West Cumberland Steel Company, also, has been blooming from the pits, while the Mossbay Iron and Steel Company is getting ready to roll rails directly. The first open-hearth works to adopt the process is the Steel Company of Scotland, which will use it in its plate-mill. On the continent, the Société Cockerill is blooming 96 per cent of its make from the pits; while in France, the DE WENDELS are preparing for its introduction. In Austria, at the works of which M. KUPELWIESER, the well-known metallurgist, has charge, soft steel ingots for plates have been put through the pits to be rolled into slabs without heating, and a new rail-mill now building is also equipped with a pit plant. An interesting statement is made by M. GREINER, who, as the result of experiments made, has found that the waste in rolling from ingot to bloom is reduced to one half of one per cent, while in rolling directly to the rail it is only one per cent, a gain in the latter case of at least two per cent. That the advantages of the soaking-pit are becoming appreciated in this country may be gathered from the fact that the Cambria and the Edgar Thomson works are about to introduce it. It may be stated that Mr. GJERS, with the object of preventing the cooling of the top of the ingots, has designed a cover, and that he has undertaken improvements the object of which is to facilitate repairs.

LEAD has dropped down to 3·70 cents per pound, under fairly large sales. An encouraging feature is the appearance of the first evidences of a speculative support of the metal, but otherwise the general feeling in this the leading market of the country is one of discouragement. The most enthusiastic, a small number in any case, do not look forward to an early improvement, but limit their hopes to maintenance of current rates. The mines have now to choose between two alternatives, either to close down or to make some effort to reduce the cost of delivery of lead to the markets of the country. The former course is one which few will care to adopt, unless special circumstances, like the fight between the Silver Cord at Leadville and the smelters, prove an inducement. An idle mine costs money, and very few of them are in a position to make immediate outlays with the hope of future compensation from higher prices. Most of the mines will therefore probably go on producing as long as they can make both ends meet, or can raise money. Their principal relief, in the mean time, must therefore come from some other quarter. They have a right to demand, and will probably urge, that others who have in the past largely profited from the industry in which they represent first hands shall also bear their share of the burden. The smelters, we know, have been sailing as close to the wind as is possible. Where the prospect of cheapening lies is in the railroad rates, which, as we have already stated, appear to show much that is mysterious. We can see no sound reason why a mining company, when it ships ore from Leadville to Denver, should pay $5 per ton, while if a smelter ships it, it should be little more than one half of that amount. The nominal rates from Leadville to Pueblo or Denver are $12 per ton for bullion, and $10 from Denver to Kansas City; but how much cutting there is under these figures it is difficult to get at, and yet the profit must be great when compared with the rate from Kansas City to St. Louis, which is only $2.80 per ton. Nobody will demand that the railroads haul base bullion for bare cost or even less, but the impression is general that they might accept much lower rates than those rumored to be paid by "insiders." If the refiners gave the benefit of the reduction to the smelters, and they in turn were to ease up on smelting charges, the miners could meet current prices of lead.

Digitized by Google

IT is satisfactory to note that a ray of hope has been cast upon at least one important industry, the pig-iron manufacture, by the elaborate statistics just published by Mr. JAMES M. SWANK, Secretary of the American Iron and Steel Association. The following table will show at a glance to what an extent production has accommodated itself to the great shrinkage in current demand, and it is only necessary to add that of all branches of the iron trade the blast-furnaces are the slowest to so adapt themselves. It costs a good deal of money to blow out a furnace and blow it in again, and the temptation to keep on working is increased by the fact that pig-iron, more than any other product, is a staple article, there being no consideration as to assortment, etc. A rolling-mill can be shut down in a day and be started at short notice, and can not so easily pile up stock.

CONDITION OF THE BLAST-FURNACES.

Kind of fuel.	In blast Jan. 1.	In blast July 1.	In blast Nov. 1.	Going in Nov.	Going out Nov.	Out of blast Nov. 1.
Anthracite	161	125	117	3	3	104
Charcoal	129	98	98	7	6	144
Bituminous	127	111	116	9	6	107
Total	417	334	331	19	15	355

The great decrease is in the anthracite furnaces, of which 44 have blown out since the beginning of the year. The furnaces using bituminous coal or coke as a fuel have decreased in the number working very slightly, only eight, taking into account those noted as preparing to blow in this month. The decrease with them will, we presume, become more marked when some of the rail-mills still running on orders stop.

The same state of affairs is reported, fortunately, by the quantity of stock, and the showing is more satisfactory now than it was a few months ago, when it was found that the stocks had increased from 383,655 tons on January 1st to 528,590 tons on July 1st. Since then, the figures have changed as follows:

STOCKS OF PIG-IRON IN MAKERS' AND AGENTS' HANDS—GROSS TONS.

	July 1.	Nov. 1.
Bituminous	196,099	128,830
Anthracite	186,735	159,521
Charcoal	145,756	145,003
	528,590	432,354

When it is considered that consumers have run down their supplies notoriously low during the long period of hand-to-mouth buying, it will be conceded that the trade is getting down to "bed-rock." It would be idle to deny that there is not much prospect of a sustained improvement during the winter months, which are generally dull; but there is every assurance that the business is now in a very sound position statistically, and that the first signs of returning activity may witness a reaction which, under the conditions, is likely to be rapid and well sustained.

CORRESPONDENCE.

Mill Statistics.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: It is encouraging to find in the last number of the JOURNAL (p. 309) a plea by Mr. Stetefeldt for more complete and accurate statistics of metallurgical work, especially in our mills for extracting the precious metals. That there is room for great improvement there can be no question, but we can scarcely expect perfect work in a perfect system within the bounds of the cost which mining and milling companies are willing to assume. The excellence of such work must long continue to be relative and not absolute in most of our mills; for very few companies are willing to pay expert chemists and assayers, and to sustain a proper laboratory in which accurate work can be executed. The results obtained by the assays and tests are generally approximations, and must be so received.

Mr. Stetefeldt's criticism of my commendation of the statistical tables of the Alice mill in 1881 is just to a certain extent. To me, the statistics were worthy of commendation because so much more full and complete than we usually find. Mr. Stetefeldt looks for the defects, which unquestionably exist; but the *effort* of the management was in the right direction.

In regard to the fact that the product was greater than the assays indicated, and my suggestion in explanation of it, it should be said here that the last paragraph of the sentence quoted from my report contains a typographical error; the word "experienced" should be "explained," and the sentence should read, "*It is not yet clearly explained, but is a well-ascertained fact, that the product overruns the assays.*" Experienced is the wrong word. The fault most likely lay in taking the samples; the full quantity not being represented in the assays. W. P. BLAKE.

NEW HAVEN, CONN., Nov. 22.

A Request for Specimens of Construction Material for Compression Tests

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: For some years past, I have been making investigations on metals and alloys of all kinds, and have arrived at a point where I am very anxious to secure specimens for the purpose of studying the effects of compression. Will you be good enough to announce the fact through your JOURNAL, and ask the manufacturers of metals and alloys of any kind to send me specimens for that purpose? The specimens I wish should be of the following dimensions: For each investigation of compression, two inches in diameter and three inches long, three pieces being required for each examination; two pieces each one inch in diameter and four inches long; and from one to five pounds of the same metal or alloy for each examination. I should like to make at least three examinations, which will make fifteen pieces in all of each metal—nine of the larger size, six of the smaller, and not less than five pounds of the filings. I desire as much material as possible, as the expense of these investigations will be very great, and as I am making them for scientific purposes only, without remuneration of any kind, in the hope of discovering some facts which will be useful to manufacturers. I shall also be very glad to make comparative tests other than compression, and also analyses of the metals and alloys for their actual cost to me, making no charge for my own time and services.

The results I have already obtained are such as lead me to believe that the results of the investigations I am about to make will be of great interest to all persons using metals of any kind for construction.

A few very liberal gentlemen and firms have supplied me with the amount necessary for the investigations on compression; but I have no funds with which to make the comparative tests on tension, and on torsional and transverse strain, and I am therefore willing to make them for their actual cost to me, and request your kind interest in making my purpose known to your readers and asking their assistance. Yours truly,

NEW YORK, Nov. 16. THOMAS EGLESTON

Is Alumina an Acid or a Base in Singulo-Silicates?

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: I was much interested in a few suggestions made by Mr. Henry M. Howe in the JOURNAL of November 17th, and from having been professionally associated with him in metallurgical work, realize that any statements made by him are entitled to respect. But I desire merely to say a few words in confirmation of a suggestion that he throws out, and that my own experience substantiates to a considerable extent, although the question of exactly what *rôle* alumina plays in the formation of slags is far too deep and complicated to be definitely settled by any single series of observations.

During the years 1872 and 1873, I was engaged in smelting the ores of Mount Lincoln (Colorado) and vicinity in a blast-furnace. They were largely composed of massive heavy-spar, with some lime and silica, though with too much lead and copper to answer for amalgamation, while, on the other hand, the overwhelming percentage of baryta and lime, and the almost total lack of iron, made their smelting, with the poor charcoal at our command, a matter of the greatest difficulty. They were smelted into a copper matte, running some 700 ounces in silver and 25 per cent copper, and as, owing to the high percentage of heavy-spar, the matte often fell below this grade, it was frequently found necessary to calcine and resmelt it with pure siliceous ores, to bring it up to the proper grade for shipment, or for home treatment, by a modification of Patera's method, which I carried out toward the last, and while the Moose mine was in its glory. These brief explanations being necessary to show the quality of ore we had to deal with, I will come to the point suggested by Mr. Howe. He asks, "May it not be that, in calcareous singulo-silicates low in iron, alumina acts as an acid, while in ferruginous ones low in lime, it acts as a base?" My experience confirms this entire suggestion, as will be seen. I have assumed that baryta may be regarded as replacing lime to a great extent, and without going into accurate figures, my old smelting records not being at hand, I can distinctly affirm that, when producing a slag high in lime (and baryta) and low in iron, with only about 24 per cent of silica, an addition of a highly aluminous ore, carrying very little silica, produced almost the same effect as the addition of an equivalent amount of nearly pure quartz. This was first discovered by one of those fortunate accidents that often do more toward rendering a doubtful enterprise successful than the most carefully laid plans. For some weeks, we had been running with the very basic slag mentioned above, which gave us a great deal of trouble, being so pasty that it only flowed with difficulty, and constantly carried out grains of matte, requiring to be resmelted in considerable proportions. I could easily remedy it by the addition of silica, but having no siliceous ores at my disposal, excepting some that carried a large amount of heavy-spar, I found it unprofitable to add a sufficient amount of barren quartz to obtain such a slag as I desired. In this dilemma, I purchased a few tons of ore of a very peculiar nature from Buckskin Gulch. Analysis showed it to consist largely of alumina, with some silica, of course, and it carried about 90 ounces of silver to the ton as sulphide of silver, scattered through it in little specks and nodules. I regarded it as an ore only fit for amalgamation, and yet apprehended considerable difficulty even by that method, owing to its clayey nature. Yielding to the solicitations of my head smelter, as ignorant a man as ever lived, though a good smelter, and who fancied the ore would make a good flux because he had once used some clay iron ore that looked like it, we began its use cautiously, and with the most excellent results. Not to make too long a story of it, I will merely add that we contracted for a large quantity of the ore, and soon came to regard it as our stand-by for all ores carrying too high a percentage of lime and baryta. So much for alumina as an acid in slags high in lime and low in iron.

As time went on, several gold mines were opened in Montgomery, Mosquito, and the neighboring districts; and instead of being short of siliceous material, we were crowded with it, as these gold ores were mostly surface quartz, from which all the pyrites had long since disappeared, and though well stained with iron oxide, carried over 90 per cent of silica. They would have been best treated in a stamp-mill, but there being none running in the district at that time, there was no market for them except at the smelting-works, and as we could purchase them pretty much at our own price, and many of them contained from two to four ounces of gold per ton, we soon were overstocked with them. It so happened that, at the end of our autumn campaign, I had smelted up all our stock of Moose and other heavy-spar ores, and had on hand merely a quantity of the siliceous gold ores, and a lot of calcined matte, with which I proposed to smelt through as much of these gold ores as possible. On calculating out my slag, I despaired of nearly finishing up my gold ores; but my smelting foreman, having a natural desire to see every

Digitized by Google

thing cleaned up neatly, and recognizing the impossibility of fluxing the large pile of quartz with our little remnant of calcined matte, reasoned that our clay ore, of which we could always obtain a sufficiency at short notice (though much lower grade than I at first described), being such an admirable flux at one time, ought to be equally good under all circumstances; and taking advantage of my absence and the temporary delegation of my authority to him, proceeded to carry out this exceedingly simple and ingenious theory, and curiously enough, with such satisfactory results that a large heap of almost pure quartz was smelted with the addition of a very little iron, and a considerable proportion of alumina, the slag being perfectly clean, but more like glass than any blast-furnace slag that I ever saw before or since. I think this gives us a right to speak of alumina as a decided base. I fully recognize the impropriety of attaching any weight to such a very rambling statement, unsupported by analyses or exact figures. But both analyses and exact figures were made at the time, and are now among my possessions, and I merely have stated the very strong impression made on my mind by my investigations at that time.

I need hardly say that my smelting foreman regarded the laboratory work with the utmost contempt, and considered (and very justly, as it happened this time) that he could judge by eye what flux was needed better than the "boss" could with all his laboratory work, although I fear that, if I had taken up his offer to smelt any thing, even fire-brick, as he insisted he could do in his excitement, if he "only had enough of that Buckskin clay for a flux," he might not have been so uniformly successful.

I trust Mr. Howe may feel gratified at having arrived at the same results by a course of reasoning. EDWARD D. PETERS, JR., M.E.

ANSONIA, CONN., Nov. 1.

Is Alumina an Acid or a Base?

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: In the last number of the JOURNAL, Mr. H. M. Howe asks, "Is alumina an acid or a base in singulo-silicates?" and requests more information on this point.

Perhaps the behavior of the slags obtained in smelting the franklinite residuum for spiegel may be of help. The slag is normally of about the following composition: SiO_2, 34·5 per cent; Al_2O_3, 9·5 per cent; MnO, 12·5 per cent; FeO, 2·5 per cent; CaO, 32 per cent; MgO, 9 per cent; being nearly a singulo-silicate, if the alumina is present as a base. Any increase of either silica or alumina causes the slag to appear and act as if it were more acid and to take up more manganese. In fact, I am more afraid of the effect of an excess of alumina on the grade of the iron than of an excess of silica.

I know of one spiegel furnace using similar residuum where, when a very poor coal was used (I was told it contained 27 per cent ash) the slag contained about 30 per cent of silica and 15 per cent of alumina, and the furnace made gray iron containing about 8 per cent of manganese. On drawing the charge so as to get a slag of about the composition I have given above, it made 15 per cent spiegel. The same effect (lowering the grade) would have been produced if the slag had contained a normal quantity of alumina and an excess of silica.

These slags being made in larger and hotter furnaces than is usual with slags so basic and so high in oxides of the iron group, may aid in forming a more general conclusion than if lead slags only were considered. My own opinion is that, where silica is high and alumina is low, the alumina acts as a base; but where silica is low and alumina is high, it acts as an acid; in other words, the alumina has a tendency to form a slag of about the same acidity, and plays whichever part is necessary to effect this result. Yours truly, GEORGE C. STONE.

NEWARK, N. J., Nov. 19.

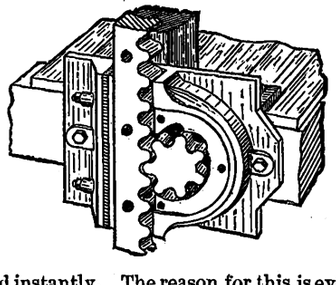
O Wise and Just Reporter!

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: The following incident will be interesting and a warning to the profession. A few weeks ago, a gentleman called at my office, introducing himself as a reporter for a paper which we will call the *Weekly Scientific Terror*. He stated that he had noticed the issue of a patent granted to me for a new metallurgical process, and wished to publish an account of it in his paper. Would I give him the necessary information? I assured him I would take great pleasure in doing so, and gave him a concise description of my "improved process for treating sulphides, obtained in the lixiviation process with sodium hyposulphite," which he took down by "short-hand." About a week later, a reporter No. 2, from the *Weekly Scientific Terror*, handed to me a voluminous manuscript for "correction." It was headed: "*The Treatment of Ores—A New Patent just taken out by a well-known Mining Engineer.*" The article commenced with a most favorable notice of my professional achievements; noticed "an able paper read before the American Institute of Mining Engineers;" and finally came to the "last patent," to be especially considered. I felt so highly flattered by this kind and unsought-for attention that I actually blushed, and cried out: "O wise and just Reporter!" After giving the "claims" of the specification, the article ended as follows, namely: "Mr. Stetefeldt said yesterday to a reporter for this paper, in an interview at his office, that the lixiviation process was coming into general favor in place of amalgamation, and is now in use in important mills in Nevada and elsewhere. The old method was to roast the ores in a reverberatory furnace, and then to melt the orders and material" [this stands for "roasted material," I suppose] "in a crucible with scrap-iron, to obtain bullion together with a certain amount of matte containing copper and silver. There is a considerable loss in drying sulphides—sometimes as much as four per cent—whereas, by the lixiviation process, the sulphides do not need to be dried and roasted, and there is no chemical loss, but refined bullion is produced, and without any copper matte."

After reading this, I felt stunned. Did I say all this to you, O wise and just Reporter? I felt as if I was a sulphide after losing 4 per cent of silver by drying; indeed, I felt as if I had gone through the whole lixiviation process, and been turned out as copper matte. Reporter No. 2 then said: "Of course, you wish to have a few hundred copies (at 12 cents per copy) of the *Weekly Scientific Terror* with this article for distribution!" A quick calculation how many "Havanas" and how much "Liebotschaner" this would represent brought me back to my senses. I made some very unkind remarks about the scientific ability of the editorial staff of the *Weekly Scientific Terror*, and vehemently protested against taking several hundred copies of their valuable paper. Reporter No. 2 finally proposed that I should write an article myself, but not "too good;" otherwise, the readers of the paper would suspect that it had been written by the inventor himself. "Can you do it in a week?" "In half an hour," I said. "Well, then, I shall call for it on Friday morning." Friday morning came, but Reporter No. 2 did not! I am afraid I have hurt the feelings of the *Weekly Scientific Terror*.

NEW YORK, Nov. 19. C. A. STETEFELDT.



[Referring to the above, we may state that, during the past few months, four similar cases, all the doing of the *Scientific T.*, have come under our notice in this city and in Philadelphia. In one instance, the only one in which the operations of the schemers were successful—the victim being a manufacturer of straw goods, if we remember correctly—a gentleman came to ask our advice. In the rush of business, he had listened to the reporter of the *Scientific T.*, and had signed an order for a few hundred copies, without, as it occurred to him later, making any inquiry as to the cost per copy. He feared that an exorbitant charge might be made, and went off relieved after having received assurances of the doubtful legality of such a course. We need hardly add that, as a new venture in journalism, the *Scientific T.* does not deserve encouragement.—EDITOR ENGINEERING AND MINING JOURNAL.]

METALLURGY AND ENGINEERING AT THE BOSTON EXHIBITION.

Special Correspondence of the Engineering and Mining Journal.

(*Continued from page* 309.)

Canfield's Safety-Stop.—This simple and apparently very effective little stop shown in the cut, though designed for ordinary elevators, seems quite applicable, with certain modifications, to mine shafts. It consists of three parts: A stout rack strongly bolted to the guide-timbers, and having short but thick and wide teeth; a small but strong cast-iron guide-box, with a recess which is toothed on its upper side; and a pinion, wholly unpivoted and playing freely in the recess in the guide-box, and gearing into the teeth of the rack. These parts are shown in the accompanying cut, in which, however, the teeth on the upper side of the recess of the guide-box do not stand out very clearly. As the elevator rises and falls, the little pinion plays loosely in the recess, its teeth gearing into those of the rack, and barely avoiding contact with those of the guide-box, its own weight keeping it always against the bottom of the recess. But if the downward speed of the cage is rapidly increased, the little pinion becomes jammed between the teeth of the rack and those of the upper side of the recess, and the

cage is thus stopped instantly. The reason for this is evident. The pinion does not fall freely, its descent being retarded or hampered by its playing in the teeth of the rack; this retards its descent so much that any considerable increase in the downward speed of the elevator causes the guide-box to overtake the pinion, so that the latter now comes in contact with the upper and toothed sides of the recess. An advantage of this is, that it is apparently instantaneous. I carefully watched its action when the elevator rope was suddenly detached, and the car appeared to stop before it had fallen an inch and a half. Of course, much less strain is caused by stopping a car before it has fallen an inch than by stopping it after it has acquired momentum in falling a considerable distance. To prevent the stoppage being so sudden as to seriously strain the cage, rubber plates are introduced in the guide-box itself, and between the cage timbers and the flange of the guide-box which supports them.

One objection to the stop occurs to me. Its sudden action depends on there being but a small amount of play between the pinion and the inclosing recess. Now, in the years which might elapse before the breaking of a rope, and in which all care and concern for the safety-catch might have vanished, the teeth of the pinion might have become considerably shortened by their constant sliding friction against the bottom of the guide-box, which would itself be worn away by the same cause. This wearing away of these parts would destroy their adjustment, on the accuracy of which the rapidity of action of the catch seems largely to depend. Mr. Canfield states that he has tested this point, and it appears that the teeth wear into such a shape that they jam and stop the cage while they are still long enough to act promptly in case of breakage of the rope. Of course, these heavy iron racks would be too costly for deep shafts, and I have only described this stop because it occurs to me that it might be easily modified to suit wooden guides. If the pinion had sharp saw-teeth, and if the upper side of the recess which contains it were lined with wood or rubber, it should jam between this lining and the wooden guide on a sudden increase of the rate of descent of the cage, just as the present pinion does between the racks and the recess. It would cost but little to put two or even four such stops on each side of a cage in addition to any other safety-stop desired, which they would thus reinforce. They would be an anchor to leeward.

Emery-Wheel Flanges.—On account of the many and fatal accidents to metal workers from the bursting of emery wheels, Ware's anti-bursting flanges deserve attention. We are told that the number of persons thus injured averages as high as from eight to ten per annum, of whom nearly

Digitized by Google

fifty per cent are killed. To diminish the dangers from this source, Ware's emery-wheel flanges are made very broad, nearly as broad as the wheel they hold, and are studded over on their insides, that is, on the sides which come in contact with the emery-wheel itself, with rubber buttons, set very tightly into little recesses in the flanges, and projecting perhaps an eighth of an inch from their surface. These buttons grasp the emery-wheel very firmly when the flanges are screwed together tightly, so that when a wheel bursts the fragments can not fly out, being held in place by the rubber buttons. In some cases where wheels with these flanges have broken, the fracture has not been discovered until the wheel was stopped at the end of the shift. The Union Stone Company, which exhibits these safety-flanges, has also a swing-frame grinding and polishing machine, which consists in a swiftly-revolving emery-wheel suspended and freely swinging, its hight and position being readily and easily adjustable. It is especially designed for grinding large castings, etc., which it would be difficult or inconvenient to grind with the ordinary stationary wheels. It is hung from above with a jointed frame, and is swiftly revolved by an endless rope, whose stretch is compensated for by simple mechanism.

This company's surface-grinding machine also deserves attention. It is practically a small planer or milling-machine, in which the cutting is done by an emery-wheel instead of in the ordinary way. The piece to be operated on is fastened to a table, by jaws, etc., and the table travels back and forth beneath the emery-wheel, just as the bed of an ordinary planer does. This device might advantageously replace the planer and milling-machine in working exceedingly hard substances, such as the surfaces of dies and punches.

Messrs. Hill, Clarke & Co., of Boston, have an interesting display of *Iron-Working Machines*. Among those with features at once novel and interesting may be mentioned their large Brainerd milling-machines and their fine hollow spindle lathes, made by Flather & Co., of Nashua. These milling machines run from 9 to 84 inches, the latter size weighing only 7000 pounds. The large sizes are advantageously replacing planing-machines for some important classes of work. The Flather lathes, in addition to the hollow spindle, whose advantages are too well known to need description here, are fitted with most excellent turrets, which enormously increase the output of work. On some classes of work, for example, on bolts, etc., of different diameters in different parts of their length, five times as much work can be done in a given time with these turrets as with a lathe unprovided with them; and once set by a competent machinist, they can be run by a boy on work which would require the constant attention of a man if done in the ordinary way on a lathe.

The same firm displays the *Cummer Engine*, which I will pass over briefly, as it has already been fully described in your pages. It is an automatic cut-off engine, with a positive cut-off motion similar to that of the well-known Buckeye engine, as opposed to the releasing cut-off class like the Corliss. In the Buckeye, the governor consists of two weights revolving around the main shaft in a vertical plane. As the centrifugal force throws these weights outward, they draw with them the cut-off eccentric, altering its lead, so that the steam is cut off earlier in the stroke. In the Buckeye engine, the centrifugal tendency of these weights is resisted by a pair of springs. In the Cummer engine, it is resisted by a single spring assisted by a heavy stationary counterpoise, which is connected with the governing revolving weights by an arrangement of bell-cranks. By lessening the tension of the springs in the Buckeye governor, and by lightening the counterpoise in the Cummer engine, we diminish the centripetal force; that is, the resistance which is offered to the centrifugal tendency of the revolving weights for a given radius of gyration; so that at a given speed of revolution they will fly out farther from their shaft, and thus increase the lead of the cut-off eccentric, causing the steam to be cut off earlier and reducing the speed of the engine. That is to say, the speed at which the engine will run depends, in the Buckeye, on the adjustable tension of the governing springs—in the Cummer, on the adjustable weight of a counterpoise. While both are excellent engines in design as well as in workmanship, the Cummer seems to offer a slight advantage for certain classes of work in having the counterpoise which determines the speed of the engine accessible while it is running, so that the speed can be altered to any desired extent while it is in motion, even if at full speed; while in the Buckeye it is necessary to stop the engine in order to get at the springs whose tension controls its speed.

The *Westinghouse Engine*, which is also exhibited, has several features that especially commend it for mining purposes. The engine is a single-acting, double-cylinder, vertical one, all the moving parts being contained in a closed case, partly filled with oil, into which the cranks dip at each revolution, oiling themselves automatically. The cut-off is fixed, hence it is not adapted to work where the load varies considerably and where a high degree of efficiency is needed. While, therefore, it can not compete in efficiency with automatic cut-off engines, it is far more economical than the plain slide-valve engine, since it cuts off very much earlier than the latter can be made to do. For remote places, its lightness, compactness, simplicity, freedom from repairs, and the small amount of skill and care needed to run it properly, combined with its cheapness and very good efficiency, render it attractive. It is much lighter than most other engines per horse-power, and probably far lighter per horse-power than any engine which can compare with it in efficiency. It is extremely compact. There are only about one fourth as many points where wear can take place as in ordinary engines, and it is so designed that its good performance is quite independent of wear, since all wear or lost motion is taken up automatically. The wearing parts are not adjustable, and are not touched till worn out. There are no oil-cups, not a packed joint or a stuffing-box of any kind; not a brass that can be keyed up; it is so self-contained that it is independent of alignment. These features render it possible and, in many cases, advisable for economy's sake to employ unskilled men to run it. Its cost is from 20 to 40 per cent below that of the best automatic cut-off engines, and the makers are prepared to guarantee that these engines when of 100 horse-power or upward will run with three pounds of coal per indicated horse-power per hour—which is not so far below the guarantee of the most economical non-compounding engines. Its makers claim, apparently justly, that the consumption of oil is much less than in other engines. While the valves and pistons are lubricated by an ordinary oil-pump, the cranks and cylinders are automatically lubricated by the splashing of the oil in the internal crank-case, and there are no cross-heads or slides to oil. Its freedom from repairs is well illustrated by its having run in some cases eight months continuously without a stoppage, and without any adjustment whatsoever, not a key or a nut being touched.

The *Porter-Allen Engine* is also exhibited, running under a heavy load at 766 foot piston speed, with apparently perfect smoothness, not the slightest tremor being observable. The design of this engine is probably preferred by a greater number of the most intelligent engineers than that of any other engine, and, as long as its present very high standard of workmanship is kept up, it should yield the palm to no engine yet designed. It requires, however, the greatest care on the part of its makers and of those in charge of it.

Messrs. Kendall & Roberts, of Cambridgeport, Mass., exhibit a very compact double-cylinder *Mine Hoisting-Engine*, with conical drum, the whole design being excellent. They have here also an automatic cut-off engine which has been much admired.

Glass and Porcelain.—Here we find four exhibits which deserve special mention. The Trenton Pottery Company, Trenton, N. J., has a very creditable display. Ott & Brewer, of the same city, have a really most admirable display of very beautiful Belleek china, so-called from Belleek, in Ireland, where it was first made. It is very fine, and some of it seems as thin, delicate, and beautiful as the celebrated egg-shell china, the exterior designs being very clearly and distinctly visible from the inside of the pieces on holding them up to the light, so thin and transparent is it. The Vasa Murrhina Art Glass Company, of Sandwich, Mass., exhibits very beautiful Venetian glass vases and similar designs, the aventurine and other Venetian effects being charmingly reproduced. It is stated that this industry has only just been started here, employing American workmen almost exclusively. Even leaving out of consideration the drawbacks which necessarily attend the beginning of such an industry, these products deserve admiration. The New England Glass-Works, of East Cambridge, Mass., have a very beautiful display; the most striking feature of it being their amberina glass. This ware is largely made into vases and other long articles, which are of a beautiful ruby color at one end, shading off imperceptibly into a charming delicate amber color at the other, the shading being so gradual that it is as impossible to say where the red ends and the yellow begins as it is in general to point out where a hillside ends and where its valley begins. Although a patent has been taken out for making this beautiful glassware, the method and the chemical principles involved are kept secret. As far as can be gathered, the red color is due to the addition of gold and copper to the glass. The beautiful red tints produced in glass by both cupreous oxide and oxide of gold are well known, as is also the fact that gold-bearing glass when first prepared in certain ways is quite colorless until it has been brought a second time to a high temperature, when it assumes a beautiful ruby tint, supposed by some writers to be due to a partial reduction of the trioxide of gold which they suppose exists in the colorless glass. At East Cambridge, the glass is apparently brought to the desired shape, and the end it is desired to color red is then brought close to the glory-hole, from which it is withdrawn we may guess soon after that end has reached the temperature at which the ruby color of gold is produced, and before the color has had time to extend the whole length of the piece. It may be conjectured that the yellow color is due to the presence of metallic copper, as in aventurine glass, though more finely divided; that when the end of the piece is heated, the gold is reduced to ruby oxide, the oxygen which it parts with converting the metallic copper into cupreous oxide. H.

THE HOISTING AND PUMPING MACHINERY OF THE BINDWEIDE MINE, GERMANY.

(WITH SUPPLEMENT.)

As an example of the design and general arrangement of mine machinery of modern type in Germany, we have chosen a series of illustrations accompanying a paper read by Herr Th. Peters, of Berlin, before the German Society of Engineers. We publish this week a supplement, showing the general arrangement of the plant of the Bindweide mine, near Steinebach, which we will follow in rapid succession with three additional plates, giving details of the machinery.

The mine works a system of approximately parallel veins of iron-stone cutting through the strata of the older Rhenish gray rocks. The apex of the veins and the outcrop of the strata are covered with *débris* of basalt partially decomposed and altered to a clay, which, where untouched, more or less effectually protects the mine against the influx of water. Along the outcrop of the veins, this protecting layer of clay has partly been removed by open cuts, and has partly been fissured by caves due to the collapse of underground workings, so that the surface water flows into the mine comparatively quickly. According to the weather, the quantity of water to be kept down is subject to considerable variations. Until recently, the mine had not been opened out below drainage level, but when, in 1880, the reserves had been nearly exhausted down to that level, arrangements had to be made for deep working; and in sinking a new machinery shaft, the leading considerations were to work the ore in the different levels in the shortest time and at the lowest outlay, to provide for the hoisting of both ore and men at the lowest cost, and to place the shaft so that its safety would not be imperiled by the old workings and by future mining. The position of the hoisting-engine and the boilers, in reference to the shaft, was dictated by local circumstances. It was decided to put it near the northeast side of the shaft. The pumping-engine might have been placed in any other position, but it was thought best to place it between the shaft and the hoisting-engine because the space between the hoisting-tower and the engine could thus be utilized, thus making the buildings cheaper and because the whole plant can be served much better. The drawing is so complete that it needs no further description. The measurements are all metric.

NEW YORK STATE CANALS.—The canals will be officially closed December 1st.

THE MINES AT RIO TINTO, SPAIN.—II.

The Spanish and Portuguese pyrites almost exclusively supply the chemical works of Great Britain. The Rio Tinto Company is one of the syndicate of the three largest mines, the Tharsis, the Santo Domingo or Mason & Barry, and the Rio Tinto, an agreement securing to the latter forty per cent of the English market and the monopoly of supplying the continent. The pyrites for export are carried in six trains daily, composed of 25 cars of 7 tons capacity each, to the port of Huelva, where there are shipping facilities to load four 2000-ton vessels at a time.

The pyrites treated on the spot constitute about three quarters of the entire quantity mined. Formerly, they comprised only one class, obtained by sorting out the export pyrites at the mine. Now the cobbing is much more complete and careful, the use of dynamite in blasting breaking the ore into smaller fragments. Five principal grades are sorted out, namely: 1st, smelting ore; 2d, roasting ore; 3d, ore to be subject to special treatment, in large heaps; 4th, ore to be treated by the new process; and 5th, cupriferous lead ores. The method of treatment of these different classes is as follows:

1. *Working the Rich Ores.*—Ores carrying from 7 to 8 per cent, the quantity of which has increased since opening out the San Dionisio lode, are roasted in heaps or *teleras*, in lots of 600 tons, the product being a mixture of oxide of iron, sulphates of copper and of iron, and kernels. To the roasted ore, is added siliceous raw ore carrying on an average from 2 to 3 per cent of copper, for the purpose of fluxing the oxide of iron. In smelting, old Spanish cinders, with 1·5 per cent of copper and a small quantity of limestone, are also added, the average percentage of copper in the charge being 45 per cent. Eight blast-furnaces, 16 feet high, equipped with a single tuyere, put through from 25 to 30 tons of smelting charge per day of twenty-four hours, with a consumption of 25 per cent of coke, costing delivered 32 francs per ton, and producing from 2 to 3 tons of matte carrying from 38 to 40 per cent of copper and a cinder running 0·4 per cent of copper. Assuming six out of eight furnaces to be steadily producing, the product annually would be from 5000 to 6000 tons of matte, equivalent approximately to 2000 tons of copper.

M. Cumenge gives the following analysis of a sample of this rich matte:

Copper	46·60 per cent.
Tin	26·74 " "
Lead	3·30 " "
Sulphur	21·28 " "
Arsenic	0·26 " "
Silica	0·80 " "
Silver	320 grains per ton.
Gold	4 " " "

This matte is sold in the English market.

2. *Working Roasting Ores.*—The roasting of the ores in large heaps has ceased to be, as it was formerly, the method employed for almost the entire mass treated. At one time, 300,000 tons of ore, roasting in immense heaps or *teleras*, belched clouds of sulphurous acid into the air, so that vegetation was killed for many miles around, and it was, when certain winds prevailed, almost impossible to work in the open cut, and claims for damages were pressing. Now only 50,000 tons are burning in such heaps, and the inconveniences from the fumes have ceased. The ore was and is leached in the manner to be described farther on.

3. *Ore Worked by Special Treatment in Large Heaps.*—Formerly, the ore was first roasted, as above, and was then leached, a process taking years for its completion, so that the old Spanish heaps still furnish copper. A new principle has been introduced, which, according to M. Cumenge, consists in utilizing, for the purpose of hastening the conversion of the copper into a soluble salt, the acid fumes which were formerly such a source of inconvenience. There is one large heap kept at a uniform hight. Around it, are formed smaller *teleras*, which are lighted, and upon which are thrown raw ore, and the ore roasted separately as above. The sulphurous acid produced by the combustion mixes with steam generated by the heating of the moistened heap, and thus sulphuric acid is formed. Whatever may be the theory of the complicated reactions taking place, so much is sure, that the heap composed of roasted and raw ore aggregating four millions of tons evolves no striking quantities of acid fumes. Its upper surface is watered like a vast meadow with great volumes of water, and from its lower portion drain brooks of cupriferous solutions. The latter are conducted by wooden channels or lead siphons into large masonry reservoirs lined with cement or with a mixture of plaster and tar. In passing through these reservoirs, the solutions come into contact with cast-iron or wrought scrap, on which the copper is deposited, while the iron goes into solution. This cement copper or "precipitate" is given the local name of *cascara*. Recently, this product is purified by dissolving out the slightly arsenical subsalts of iron by washing with slightly acidulated water and then with pure water. It is necessary then to dry it only, instead of calcining it in reverberatory furnaces, as formerly, to drive off part of the arsenic.

The precipitate which is sold in England carries from 75 to 80 per cent of copper. In order to avoid the expense of sacking, the waste in transportation, and the deductions for moisture, two large melting and refining furnaces are now constructing.

4. *Treatment of the Smalls by the New Process.*—All the fines and smalls produced in mining and sorting are to be treated by the Doetsch process, which has been applied with success on a large scale after some experimenting. Its principal advantages are, that it avoids previous roasting, reduces the quantity of iron for precipitation, and shortens the time in which returns are obtained. It comprises three operations: the solution of the copper in the raw pyrites by a liquor containing perchloride of iron, the precipitation of the copper in the solution so obtained by iron, and the regeneration of the perchloride liquor. The theory of the process is developed by M. Cumenge as follows:

The copper exists in the ore in the form of bisulphide and protosulphide of copper. In presence of perchloride of iron, these compounds are affected as follows:

$$CuS + Fe_2Cl_6 = 2FeCl + CuCl + S.$$
$$Cu_2S + Fe_2Cl_6 = 2FeCl + CuCl_2 + S.$$

What constitutes the success of the operation is the fact that the perchloride of iron in dilute solution attacks the copper pyrites rather than the iron pyrites, the latter practically remaining almost entirely unchanged. In the place of perchloride of iron, a solution of sulphate of iron and sea-salt is used, which, by double decomposition, produces perchloride of iron and sulphate of soda, the latter salt facilitating the reactions. The perchloride liquor is uniformly distributed by means of platforms on the top of the heaps. Vertical chimneys and horizontal flues, built up of dry masonry, give access of air. When the heap is builing up, the ore is mixed with one half of one per cent of salt and a like quantity of sulphate of iron, the hight of the heaps varying between 13 and 16 feet. When systematically moistened, ore containing on an average 2·68 per cent of copper has yielded 1·34 per cent, or one half, at the end of four months, while at the end of two years 2·20 per cent is extracted. From one eighth to one fifth of the entire quantity of copper in the ore is leached out in the first ten days, and the action becomes slower. It is the intention to take advantage of this, and three large basins are constructing to do the preliminary leaching, and then only will the ore be piled in heaps to follow the course thus far adopted. By way of comparison with the old method of roasting and leaching with pure water, it may be stated that only 1·10 per cent is extracted after the first two years. The preliminary mixing with a perchloride liquor before forming heaps will probably reduce the time required for the heap-leaching also, and it is expected that the ore will be practically exhausted at the end of two years. The liquor, as it comes from the heaps, carries from 5 to 7 kilograms of copper per cubic meter. The copper in this liquor is precipitated by means of iron according to the following formulæ:

$$CuCl + Fe = Cu + FeCl.$$
$$Cu_2Cl + Fe = 2Cu + FeCl.$$

As the solutions contain almost exclusively protochloride, from which one equivalent of iron precipitates two equivalents of copper, it will be readily understood that the consumption of iron is reduced. A record kept for two years proves that the quantity of pig-iron required for precipitating one of copper is 1·12 in the new process, against 1·56 to 1·70 in the old method. The precipitation is carried out in long, shallow masonry basins filled with pig-iron and old rails, which are cleaned out every four or five days, the product being a precipitate carrying from 80 to 85 per cent of copper. In the best precipitating-vats a cupreous mud, called *papucha*, is collected, which, being lower in grade, is smelted. The solution, after the precipitation, contains only 20 grains of copper per cubic meter.

In order to regenerate the liquor, containing almost exclusively protochloride of iron, a current of chlorine gas is passed through it. In order to produce the latter, a mixture of salt and sulphate of iron, collected on the banks of the Rio Tinto River or obtained from the old Spanish ore-heaps, is calcined in a reverberatory furnace, free access being given to the atmospheric air. In order to avoid the generation of hydrochloric acid, and transform into chlorine any small quantity which may be produced, a small amount of oxide of manganese is added to the charge in the reverberatory. The gas evolved in the furnace is conducted into a tower, to the top of which the solutions to be regenerated are pumped, and down which they descend in a shower, absorbing the ascending chlorine gas on the way.

There are now two heaps working containing 150,000 tons of ore each, and a third is preparing. A steam-engine is used to move the liquors, and the corroding action of the liquors upon pumps and pipes has been overcome, so that now the Rio Tinto Company is producing weekly 50 tons of copper by the new process. In order to provide for the development of this part of the business, a large mill has been constructed in order to crush ore to the size required for this special treatment, there being nine Blake crushers and a number of sets of Cornish rolls, with ample screen capacity.

5. *Working the Lead-Copper-Ores.*—There is at Rio Tinto a stock of several thousand tons of ores carrying considerable lead and a percentage of silver not yet sufficiently well ascertained. As yet, nothing has been done to provide for its treatment.

Estimates of Cost.—M. Cumenge has made a series of estimates of cost of production, which he considers will suffice to give a clear idea of the possibilities of the enterprise. He does not claim for them absolute accuracy, but he adds in a supplement a number of figures from other sources which corroborate his data and show his conclusions to be conservative.

COST PER TON OF COPPER DELIVERED IN ENGLAND IN THE FORM OF PRECIPITATE.

Fine Ore taken from Open Cut.

		Francs.
Dead-work and stripping		1·00
Mining, per ton of pyrites, labor, powder, dynamite, etc...	0·80	
Crushing, sorting, loading, and transportation	1·20	
Maintenance of tools, rolling-stock, and track	·50	
Total mining cost:		2·50
Discharging, making canals and heaps, general labor	0·30	
Water	0·25	
Total roasting and leaching cost:		0·55
Charging and discharging tanks, cleaning, maintenance	0·80	
Drying, purifying, and soaking precipitate	0·15	
Pig-iron, 17 kilos, at 100 francs per ton, delivered	1·70	
Total cost precipitation:		2·65
Cost per ton of ore		6·70
Cost of copper:		
100 tons pyrites, yielding one ton of copper in one year at 6·70		670·00
Freight to Huelva		2·50
Freight to England, insurance, cost of marketing, assays, differences in moisture		27·50
Cost of production		700·00
From ore from underground workings:		
Mining, labor, dynamite, etc	2·00	
Loading, hauling, discharging, sorting, and reloading	1·75	
Maintenance of plant and track	0·75	
Cost of mining:		4·50
Roasting and leaching		0·55
Precipitation		2·65
Total per ton of ore		7·70

Under the same conditions, the cost of production per ton of pure copper delivered in England in the form of precipitate would be 800 francs.

Digitized by Google

The further working of the heaps, after the extraction of one per cent by the old method during the first year, would cost per ton of copper:

Water	25	francs.
Precipitation	265	"
Transportation	30	"
	320	"

M. Cumenge reaches the conclusion that, as one half the copper is extracted from ores taken from the open cut and one half from subterranean workings, the cost per ton of pure copper laid down in England would be 750 francs, or £30 sterling.

The cost of the ore shipped for export delivered in England, would be:

Mining	4·00	francs.
Freight to Huelva	2·50	"
Freight, insurance, etc	17·50	"
	24·00	

The prices obtained for ore are a matter of agreement. The sulphur fetches 6 francs per unit, or 30 francs per ton, on the basis of 48 per cent. The copper, 2·5 per cent wet Cornish assay, would bring, on the basis of £65 per ton for Chili Bars, 27·75 francs, making the total 57·75 francs, or a profit of 33·75 francs per ton, at the prices then prevailing, but now reduced so that it is probably less than 30 francs.

M. Cumenge gives the following interesting estimate of the cost of producing a ton of 85 per cent precipitate by the new process, based upon the results of four months' working, during which 224 tons of precipitate were made:

Salt for chlorine and for mixture, 0·62 ton, at 68 francs	17·06	
Salt, 0·20 ton at 12 francs	3·00	
Coal, pump, labor	63.75	
Cost of dissolving		83·81
Iron, 1·12 tons	104·00	
Labor	77·16	
Cost of precipitation		181·16
Materials	5·25	
Repairing vats	11·87	
Freight on materials and machinery	4·00	
Maintenance of track	1·20	
Salaries and houses of employés	5·72	
General expenses		28·04
Total cost		293·01
Or per ton of pure copper		345·00

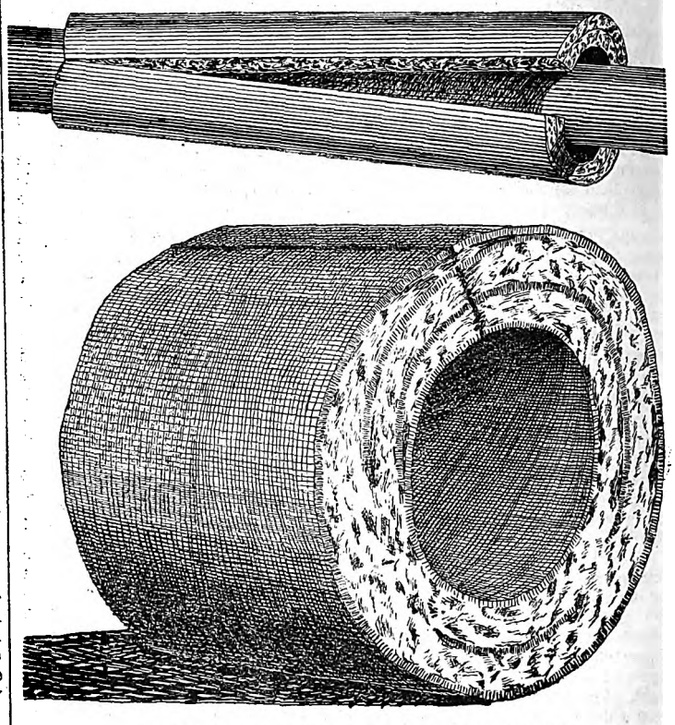
As the yield is at the end of four months 1·34 per cent, 75 tons of ore suffice to produce one ton of pure copper:

75 tons ore at 4 francs	300	francs.
Cost of treatment	345	"
Freight to Huelva, England, and miscellaneous expenses	30	"
Total	675	"

The water question is one that has been the subject of much thought at Rio Tinto. When it is considered that it takes 70,000 cubic feet of water per ton of cement copper produced, and that the quantity falling in the Rio Tinto water-shed is not more than 70,000,000 cubic feet, it will be understood that the production reached its maximum with 10,000 tons. This question has been entirely put at rest by the gigantic work undertaken, and now nearly finished, in the Odill basin at Campo Frio, ten kilometers from Rio Tinto. A dam 80 feet high has been built which will collect the rain-fall of 35 square kilometers, the capacity of the lake formed being about 10,000,000 cubic feet of water. A fifteen-inch pipe brings the water to Rio Tinto, and the supply will be sufficient to vastly increase the producing capacity of the mine.

THE ARLBERG TUNNEL.—The fragments of rock dividing the eastern and western galleries of the Arlberg tunnel were removed November 19th, in the presence of a notable assemblage. Baron Von Friedenthal, the Austrian minister of commerce, delivered an address in German and Italian. There was much enthusiasm. A special train passed through the tunnel from east to west.

MESSRS. KEUFFEL & ESSER, of this city, have just issued a new catalogue (price 50 cents) descriptive of the drawing materials which are their chief specialty, and of which they are both manufacturers and importers. They illustrate also their surveyors' tapes, chains, bobs, rods and poles, mining lamp and plummet, pocket compasses, sun-dials, levels, sextants, pedometers, transits, anemometers, etc.



MR. JOHN MILLER, an enterprising business man and respected citizen of Altoona, Pa., died at his home in that place November 13th, at the age of seventy-eight years. While engaged in the coal business, a number of years ago, the deceased discovered and opened the celebrated "Miller vein" of coal in the Alleghanies, which has since been operated with such great success by the Cambria Iron Company. It is one of the finest coals in the State and makes excellent coke.

ECONOMIZING SPACE.—The New York *Sun* "condenses" as follows: "Of all the plans for economizing space," said a patent lawyer, "the man who just left this office evolved the funniest. He had a drawing of a sleeping-car that he wished me to get patented for him. He thought it was a good thing, and would hit the railroad managers hard, because it nearly doubled the number of berths in a car. I saw right away that the beds were ridiculously short. I asked their length. 'Four feet and a half,' he replied, 'and that's plenty long enough. A careful investigation has proved to me that there is really no use in a bed being as long as the person in it. Not one man in fifty ever sleeps straightened out, and women invariably draw up their knees, so that they don't require more than a four-foot bed. It is a discovery of this fact as to sleeping that I wish to protect by the patent. I should stick up in each compartment a printed notice explaining that the middle of the car is much safer than the sides, and, therefore, the closer their legs are hauled in toward the center partition, where their heads are to be, the less they are liable to be hurt by collision.'" The lawyer did not take the case.

A VISIT TO AN ASBESTOS MANUFACTORY.

We have had occasion recently to visit the factory of the Chalmers-Spence Company in this city, which has made the manufacture of many different articles from asbestos fiber a specialty. It needs only a cursory examination of the different processes which the raw material must undergo to appreciate the fact that it requires considerable experience and judgment to make the proper choice. It is convincing too on the point that asbestos may appear to possess every requisite, and yet the same may be practically valueless. The first desideratum is length of fiber; and secondly, a certain toughness and elasticity which many specimens do not possess. We have seen good-looking material which was "rotten," and would warn those of our mining friends whose spirits may run high upon the discovery of asbestos, not to allow their hopes to run away with them, until the material has been examined and tested by parties whose experience in manufacturing has made them competent judges.

The rock, as it is received by the Chalmers-Spence Company, is put through a machine on the ground floor, which by a system of rollers separates the fibers from one another. The material so obtained is carded, by which the rock is taken out and the fiber is separated according to length, the shortest being used as paper stock. It is sent to paper-mills, where board is made of it. The longest fiber is made into yarn on a special machine, the product serving as the basis of all the asbestos textile

CHALMERS-SPENCE PIPE COVERING.

fabrics made. For cloth, there is a special loom. Other grades of the fiber are made into felt by a special machine, which has appliances for insuring uniformity of thickness and the needed degree of cohesion.

Beginning with the yarn, it is used in that form for wick packing for valve-stems; in larger form, it is applied for packing of all kinds; and to better adapt it to that purpose, the packing is prepared with a variety of lubricating materials. The asbestos cloth is used in many different ways which it is needless to enumerate. The boards and sheathing made from the paper stock are shaped into gaskets, and into such forms as are required for steam-joints, etc. The sheathing is used as such for insulating purposes and as a protection against fire between floors. One of the most recent of these applications for fire-proofing is inside of elevators, which have of late years proved such disastrously convenient avenues for the spread of fire in large buildings. It appears much more suitable for that purpose than the sheet-iron lining of elevator shafts, which we have had occasion to notice in some recently finished buildings. As we shall note farther on, asbestos board enters largely also into pipe and boiler coverings, which form the most important outlet for the bulk of the asbestos manufactured. The methods of manufacture of the many varieties of non-conducting coverings are simple. The latest form adopted by the Chalmers-Spence Company is that shown in the accompanying engravings.

As will be seen, it consists of a sheet of asbestos board, upon which is laid a layer of asbestos felt. They are together wrapped into a circular form, so that in section the board has the shape of a spiral, with layers of the loose asbestos fitting between it. The tube is simply slit longitudinally, so that it is only necessary, in order to put on the covering, to force it apart and slip it on, in the manner shown in our engraving. It is necessary to state, however, that our artist has omitted to show a flap, a continuation of the outer covering, which, when the pipe is in place, covers the joint. These movable coverings are made in sections three feet long, for any size of pipe needed. They weigh about one pound per square foot per inch of the thickness of covering. It may be of interest to state here that the Chalmers-Spence Company also makes a non-conducting plaster covering, in which asbestos fiber is used as the binding material, the covering weighing only two pounds per square foot per inch of thickness. This covering, besides its lightness, has special merit as a fire-proof material, and

Digitized by Google

is also used for fire-proofing walls, etc. A crucible made from it for purposes of experiment showed it to be capable of resisting the highest heats. The Chalmers-Spence Company also puts up coverings with an air space, using it largely for extensive surfaces as on marine boilers.

The asbestos felt, placed between an inner and outer layer of asbestos board, is also put up in square sheets about one inch thick, to be used principally as a removable covering for boilers, notably for high-pressure steam. Where hair felt is preferred, asbestos sheathing is used in the same way to protect the hair against the singeing due to direct contact with the hot surface. It will be noted that the asbestos industry has been thoroughly developed, and that in one or the other form the prepared material is made to do service for a large variety of purposes. A disposition is shown to meet the wants and fancies of consumers, manufacturers avoiding the error too often committed by those developing a specialty of insisting that there is but one way, and that is the one they have chosen. Asbestos in its many forms is now largely applied by mines, furnaces, mills, factories, and steamships, and it is a gratifying fact that, in the case of the latter, it is no uncommon occurrence for American makers of boiler coverings to be called upon to replace by articles of their own make the covering put on in England.

ADDRESS ON MECHANICS BY COLEMAN SELLERS, SR.

On November 9th, Mr. Coleman Sellers opened the course of lectures in connection with the Franklin Institute with an address on Mechanics. We are indebted to the *American Machinist* for the following abstract: The lecturer began with a review of the origin of their lecture course. During the first season, the lectures were confined to men, but in the following year ladies were admitted, and this has continued to be a feature of the meetings ever since. Although the subjects treated are principally those relating to mechanics, the attendance shows that they are found interesting to ladies.

If we consider what was the state of the mechanic arts at the time the Franklin Institute was first founded, and what is the state of the same arts now, we can form a better idea of what the lecture course was in those days and what is expected of the lecturer of the present day. In business, nowadays, we measure the success of mechanical enterprise very much by the prosperity of the railroads. I think it would be fair to take the success of the railroads as the standard of the progress of the United States during the sixty years that have elapsed since the first lecture was delivered. It was in 1824 that George Stephenson began striving to induce the people of England to build the Liverpool & Manchester Railroad. In 1825 he was laughed at as a visionary. You will find books in the library that refer to the bubbles talked of in 1825, and the contemplated Liverpool & Manchester Railroad is referred to as the wildest of all the bubbles. At that time, the term locomotive as applied to that form of engine was not invented. It was not until 1829, when that railroad was opened, that the term came into use. But we had locomotives before that time. In 1819, Oliver Evans took through the streets of Philadelphia an old scow which moved itself by steam. Evans foresaw the important factor that steam was destined to act in accelerating land transportation. He said the time would come when we should start in the morning from Washington, breakfast at Baltimore, dine at Philadelphia, and sup in New York, and that would be going at a speed of forty-five miles an hour, as fast as a bird flies. Even in 1825 the world was not ready for this. The proposition of traveling at fifteen miles an hour was laughed at. Trains might be run, but they must be slowed down to five or six miles an hour, so as not to ruin the stage coach companies!

Great advances have been made since those days, and all other institutions have moved forward keeping pace with the railroads. To the people in Wall street, railroads merely represent certain values in money. By the people generally they were viewed from a much higher plane. To those who are assembled here in Philadelphia, the railroads are the embodiment of thought, and of more value than can be measured. We see this illustrated in the Pennsylvania Railroad we are so proud of and its fine machinery.

When the Franklin Institute was founded, it was intended to carry on a school of instruction for mechanics, to impart desired instruction which could not be obtained in the public schools. The mechanic indeed must not only be a physicist in the broadest sense of the term, but there is scarcely a limit to the knowledge he must bring to his use in some way. Some one has said that a man must understand matter and apply common sense to it in order to be an engineer. The aim of our institution has been to help mechanics to understand matter and the natural laws underlying their work. In the early days of the institution, the lectures were elementary but essentially practical. They were the best that could be delivered here at the time, and could not be obtained at any other place. What has been the result of this? Gradually the people have begun to recognize the need of more information than is given in the public schools. The high school of Philadelphia is the direct outgrowth of the Franklin Institute. In this and other educational institutions, it is possible for young men to obtain excellent instruction; but so far as is possible for young men to obtain excellent instruction, much improvement training relating to the mechanic arts is concerned, much improvement is needed. It is possible to have taught in the public schools the underlying principles of manual labor. There are a few simple tools that are used in a great many trades. Their use might be very judiciously introduced in the course of study. In our early history, the workshops were not far removed from the schools. It was almost impossible to attend school from one year's end to the other. A lad had to work in the shop or on the farm for some months of the year, and he could attend school the rest of the time. What was the result of this? Its tendency was to produce good solid men who were daily applying their school instruction to workshop manipulation. Who were made by this kind of training? The men who have taken the lead in building up our system of railroads, our workshops, and our factories.

What is the result of the later system of training in the public schools? The students are separated entirely from manual labor, and their heads only are developed, and this development fitting them only for the professions of doctors, lawyers, and what not. And not one single thing has come to them that will help them to enter a workshop. There is a very simple reason for this. The teachers are not mechanics. They are not expected to be. The scholars can more easily learn the things that relate to buying and selling than what relates to mechanic arts. The instruction given in the schools must bear the teacher's idea. Very few teachers in public schools are expected to understand the principles of mechanics. The examples prepared for the scholars are not taught as having relation to mechanical work. Yet many of the calculations apply as correctly to the operations of machinery as they do to the business of buying and selling. If mechanical operations were taught in schools, it would give a rest to head labor, and the hand labor would make the brain stronger.

Mr. Sellers then reviewed at considerable length the lectures of the course and their objects, highly commending all the coming lectures.

Returning to the subject of mechanics, Mr. Sellers said there was a time when the two-foot rule and a few simple tools readily answered all mechanical purposes for measurement. There was a saying in Germany that every hair in a carpenter's head is one eighth of an inch diameter. There was a meaning in that. As a carpenter does not measure so fine as a machinist does, his measuring to a hair's breadth was measuring within one eighth of an inch. That style of measurement led to the expressions "overfull" and a "little scant," which indicated measurements sufficiently close for practical purposes. A change in this respect has come over all mechanical industries. Now the parts of machines are made interchangeable, and accuracy of dimensions must be obtained. One branch of business may need only coarse measurements, while another may require the most minute measurements and accuracy. A two-foot rule may answer for many purposes and be very convenient, but there are measurements in the works which require the use of this convenient little device which measures to one thousandth of an inch. (Here he showed a Brown & Sharpe micrometer caliper. He also exhibited a French micrometer gauge, finely graduated. This he used to measure fine metallic cubes that had been finished by tool work alone, and were surprisingly accurate.) These instruments, continued Mr. Sellers, are remarkably fine; but Mr. Bond, who will lecture during the course, is connected with a shop (Pratt & Whitney's) that makes gauges of various kinds, and there they have perfected a machine which records more closely the actual size of materials than any thing ever made before.

Every thing in nature obeys certain fundamental laws, and all mechanical movements are regulated by these laws. There are certain principles of movement called mechanical powers, as the lever, the wedge, the screw, the pulley, that are used in various forms through all machines. The building of a complex machine seems very much like the forming of a complex sentence. Letters combined form words, words combined form sentences, and sentences make books. In the locomotives that pull trains from ocean to ocean, we have combined all the mechanical elements, wheels, pulleys, levers, and screws. We have beautiful sentences in mechanics as well as in books. One maker produces better arrangements in his machines than others, and so he makes a more harmonious machine than his neighbors. In the same way, one author combines his sentences better than another.

After reading some sentences in Ball's work on mechanics, a book which he cordially commended, Mr. Sellers proceeded by the aid of models and diagrams to elucidate the principles of virtual velocities. In a clear and interesting manner he demonstrated the relations that exist between speed and power in the application of the various forms of levers to machinery.

In computing the power of machines, he continued, friction must be well considered or mistakes will be made. A considerable proportion of the power of machines is absorbed by friction, but friction is valuable to the mechanic for all that. But for friction, a locomotive could not pull a train, because the wheels would slip around without moving ahead. In fact, at first they thought that friction between the plain wheel and rail would not suffice to make a locomotive pull a train, and they proposed to lay down a rack-rail for a cog-wheel on the engine-axle to work in. This was one of the first obstacles to the success of the locomotive; but they soon found that a rack-rail was not needed. Another example of friction is rather striking. The transmission of power from the steam-engine to the various parts of a machine-shop is usually effected by a line of shafting. Now, in quite a large machine-shop, when the belts are thrown off, one man can take hold of the rim of the main pulley and turn all the shafting. Let us see what work the man is doing in relation to what the engine has to do in turning the shaft. The man employs his weight of 150 pounds to the outside of the wheel, and he would have to turn it 120 feet a minute to keep it at the speed the engine has to maintain. Thus you have between 12 and 13 horse-power consumed in running the shafts of that shop. The man does not exercise one horse-power, though he may have a cold and be a little *hoarse*. A horse-power is 33,000 pounds raised one foot in one minute. One pound raised 33,000 feet in one minute would be the same power exerted. On this basis, all engine work is measured.

By means of a Weston differential pulley-block and chain, and also the Harrington hoist apparatus, which has pulleys operated by a worm screw, Mr. Sellers showed the principle of applying power in that way. He also demonstrated the loss of power by friction in the two kinds of apparatus and in a train of wheels. The amount of pull required to operate the chains was ascertained by means of a spring balance. The different apparatus showed a striking difference of loss due to friction of the working parts, but in the best performance the loss was considerable.

Now, said Mr. Sellers, it is the want of this kind of knowledge that should be met by the public schools. That is felt in the community in the ready acceptance of things that are impracticable. It is not a new thing for persons to think that perpetual motion is possible; and it is not a new thing for people to say they have discovered perpetual motion when they know they have not. There are many cranks besides the crank that turns the grindstone, but the worst crank is the crank who is going to improve on the crank. Perpetual motion is a wrong idea. When people become pretty well acquainted with the principles of mechanics and with the laws of the universe, they can be shown that perpetual motion is impossible. Those who understand the laws relating to the conservation of energy know that no power can be obtained without the dissipation of energy. Falling water may keep a mill-wheel going continually till the parts wear out, but the water has been raised above the wheel by the sun's rays. That is no perpetual motion; it is power begotten of heat. Heat may be applied to water to tear the atoms asunder till they exist in the

Digitized by Google

form of steam which is capable of doing work; the atoms of water may be still further heated till they are separated into their elementary gases; but the work to be got from them in either case will be less than the heat energy expended. When we burn coal in the furnace of a boiler, it is converted into heat, and heat boils the water, and the water converted into steam drives the machinery, and we call it very justly the steam-engine. The steam-engine does not use all of the heat by any means; probably not more than 12 per cent of the heat coming from the coal is utilized in our best engines. What a long distance between the actual practice and what we may hope to obtain some day in the perfection of mechanism!

More than seventy years ago, a great furor was created in this country by a citizen of this State named Readheifer, who claimed to have invented a machine that would run without the expenditure of power. The pretended discovery was puffed in all directions, just as similar schemes, some of them not a hundred miles from Philadelphia, are advertised to-day, and a great many people believed in Readheifer's machine. The Legislature of Pennsylvania appointed a commission to examine the machine, and Mr. Sellers's grandfather was one of the commission. Like other pretended discoverers of marvels, Readheifer would not permit the commission to take the machine apart. This made a rigid examination difficult; but Mr. Sellers, being a mechanic, discovered that the motive power was clock-work placed in the base of the machine and applied in an ingenious way.

The perpetual motion humbug appears under various disguises. Some time ago, a great stir was caused in England by the alleged discovery of a new power called psychic force. A scientific gentleman in Philadelphia got deceived by this pretended force, and the performance of a spiritualist which he had witnessed confirmed his belief. This gentleman often talked with Mr. Sellers on the subject of this new force, and nothing seemed able to convince him of its fallacy. One evening he called at Mr. Sellers's home, and when they were conversing, another scientific friend came in. The subject of the new force was again discussed, and Mr. Sellers volunteered to show some of its manifestations. He took a round ball which he had previously prepared by putting holes through it, one of them having the form, in longitudinal cast-iron, of a trapezoid. Now, he said, here is a round ball with a straight hole through it, and he pushed a pencil through the hole to prove it straight. Then he pushed a small rope through the ball, and stretching the rope between his hands, he put it in a vertical position and made the ball descend, fast or slow, just as he wished. The credulous scientist at once concluded that Mr. Sellers was exerting mind influence over the ball, but the other set his inventive faculties to find out the trick. He guessed that the hole was not straight through the ball, and that Mr. Sellers controlled the speed of the ball by tightening the rope. This was the truth. Instead of pushing the rope through the straight hole which was there for deception, he worked it through the crooked hole, and by that means was able to control the ball. Here were two men, both of them scientific gentlemen; one of them investigated the phenomenon, and the other believed what he saw.

In the consideration of every thing that is going on in the world, in investigating matters connected with these elementary powers and other mechanical questions, you can not be too well grounded in the laws of mechanics. That will give you ability to understand the kinds of appliances that can be utilized in your work, and will guard you against deceptions.

FAST WORK IN A TUNNEL.—A correspondent of the *Railroad Gazette*, writing to that journal from Moshannon, Pa., says: "The following is a statement of working hours, number of shifts, and distance run during the month of October in the heading of the Moshannon Tunnel on the Beech Creek, Clearfield & Southwestern Railroad, near Snow Shoe, Pa. The material encountered in driving this heading was the sandstone lying immediately below the lowest or 'E' vein of the Clearfield bituminous coal formation.

"The details of the work are as follows:

Number of headings		2
Dimensions of heading	7 feet	16 feet
Distance run from October 1st to 31st inclusive		499 feet
Number of shifts		50
Hours per shift		11

"The drills used were two Ingersoll, supported on columns in each heading. The system of working was the American 'center cut.' The best work for one week of 11 shifts was 119 feet. Each heading was closely followed by a 'bench' over which ran the pipes conveying compressed air to the drills in the heading. As it was necessary to disconnect these pipes when blasting on the bench, the progress of the heading was somewhat retarded. We claim this as the best time on record, and as the question is of general interest, and a discussion of the facts most desirable, we beg you to publish this claim in your valuable paper."

Another correspondent, writing from Binghamton, says: "In the tunnel taken out for use of the south-bound track at Factoryville, Pa., on the main line of the Delaware, Lackawanna & Western Railroad, the heading was driven during the month of April, 1883, 471 feet. The new tunnel being parallel to the old one, and 16 feet of rock left between them, it was found necessary, for ventilation as well as convenience, to draw a 7-foot cross-cut through from the new to the old tunnel. There were no shafts. The cross-cuts driven in April were two, size about the same as the heading, 7 by 16 feet, making a total heading of 503 feet. Nature of rock, blue, red, and gray sandstone making a good roof, with no arching necessary. The drills used were two Ingersoll, supported on columns, in each heading. The system of work was taking out the center cut. The heading was driven in two ends and 11-hour shifts. The drills were worked by compressed air. Benches followed the heading, both worked at the same time. Care was used, which necessitated lighter blasting on account of the old tunnel, about forty trains passing through it every twenty-four hours each way, making it necessary to look after the safety of about eighty trains.

"The work was divided as follows:

North end, 246 feet heading and 16 feet cross-cut	262 feet.
South end, 225 " " " 16 " "	241 "

"This made the total of 503 feet for the month."

We believe that some of our mining friends can contribute "big records" that will match the railroad men.

FURNACE, MILL, AND FACTORY.

Hendey & Meyer, Denver, Colo., are building the machinery for the new ore-sampling works at Denver. Among other things, is a pair of three-foot crushing-rolls, said to be larger than any hitherto constructed.

Lucy Furnace, at Orbisonia, Huntingdon County, will blow out soon on account of the low price of iron. The owner is John Whitehead, the coal operator of Orbisonia.

Messrs. Reis Brothers, of New Castle, have sold their interest in Neshannock furnace to A. L. Crawford for $95,000. Mr. Crawford holds it until the organization of a company now under way is completed. The rebuilding of the furnace is rapidly nearing completion.

Owing to the continued decline in iron, the Pottstown Iron Company, of Pottstown, employing several hundred hands, announces a reduction of wages of about 10 per cent, beginning December 1st. Some other mills in the Schuylkill Valley contemplate similar action.

The Cambria Iron Company, of Johnstown, has notified its 5000 employés that on December 1st wages in all departments will be reduced 10 per cent, owing to the depression in trade.

Work began November 6th at the Kelly Nail and Iron-Works, at Ironton, and the forge department, with fourteen boiling-furnaces, is running double turn. Thursday, the 8th, the plate-mill went on, there being a single set of hands at each of the three heating-furnaces. On that day, too, a few nails were cut by way of experiment. The nail factory was started on the 14th instant, there being sixty machines in position and now in operation. The railroad from the coal mine in the back of town to the mill is now in operation, the coal being dropped from the tipple-house into the cars and from the cars into the bunkers alongside of the furnaces. When the Kelly mill gets to running full, it will give employment to about 800 hands. It is estimated that the building and operation of the mill have added 1500 people to the population of Ironton.

Five barbed-wire machines, capable of making 100 pounds of finished wire every ten minutes, and twisting 18 barbs on the wire simultaneously, and adjustable so as to make either a two or four-point wire, have just been perfected by S. M. Stevens, of De Kalb. These machines are for the Astley Wire Company's works at Joliet, Ill.

The nail and tack mills of Chess, Cook & Co., at Pittsburg, Pa., have not shut down, as was reported. No suspension will take place before the regular one ordered by the Western Nail Association.

Notice of a change of the name of the Northwestern Steel Wheel Company to the Star Wheel Company, a Chicago concern, has been filed and recorded.

The Neshannock furnace, in New Castle, with eighteen acres of land, has been sold by Reis Brothers to A. L. Crawford for ninety-five thousand dollars. William Reis will continue as manager of it.

Andrews & Hitchcock's furnace No. 2 at Hubbard, O., which has been out of blast undergoing extensive repairs, has been blown in again. The furnace has been remodeled according to the latest plans, and, when running smoothly, it is expected will produce over 100 tons of metal per day.

A report from Cleveland says that the late Amasa Stone owned 600 shares in the Kansas Rolling-Mill Company, which collapsed some time ago, and as under the laws of Kansas the stockholders of a stock concern are individually liable, suits have been begun by Myron T. Herrick, who has come into possession of all the claims against John Hay and Samuel Mather, executors of Amasa Stone, to recover $175,000.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY.

ATLANTA.—Work on the tunnel at the east end has been discontinued. The carbonate of lead found at the west end does not seem to be in such large quantity as was expected, but lying below these carbonates nickel has been found which may turn out to be a find of some importance for the camp.

TOMBSTONE DISTRICT.

CONTENTION.—The pumping machinery will be ready to start up December 1st. It will have a capacity of 700 gallons a minute.

EMPIRE.—The new shaft is down 18 feet. The course of prospecting in the old workings has been changed since the strike in the Girard, because it is

Digitized by Google

thought that the same ore-body extends into this ground, and drifting is now done in that direction, with the expectation of meeting it.

SYDNEY.—This mine lies parallel with the south extension of the Grand Central, and is undoubtedly a very promising property. It is worked through three shafts. The north shaft is down 113 feet. At this depth, a cross-cut and drift have been started. From the south shaft, a cross-cut was run, which, 120 feet west of the shaft, encountered an 8-foot body of chloride ore.

WAY UP.—No more work will be done until after the decision of the pending lawsuits.

MOHAVE COUNTY.

MATHILDE.—All the ore in the mine is high-grade copper rich in gold, of which there are at least 2000 tons in sight, and when the veins of ore in the south end of the claim have been undercut by the tunnel, a large quantity of ore will be exposed. A thirty-ton water-jacket smelter, with sufficient coke to run for two months, is at Aubrey, awaiting transportation to the smelter-site, which is located ten miles from the mine, on Bill Williams Fork, where there is abundance of water. Iron wood and palo verde grow in large quantities within a mile of the smelter-site, and can be delivered there for $4 a cord. Freights on ore from mine to smelter-site are $3.25 per ton. A road has been constructed from the mouth of the tunnel at the mine to the smelter-site.

PIMA COUNTY.

TUCSON SMELTING AND MILLING COMPANY.—The adjourned annual meeting was held at 408 Congress street, Tucson, recently. The new Board of Directors is: James H. Toole, Aaron Mason. H. S. Stevens, Samuel Hughes, R. C. Pearson, R. N. Leatherwood, Joseph C. Perry. Work will be commenced as soon as they can contract for enough lead flux to insure a steady run. There are sufficient iron and lime flux [illegible]. Then the sampling-works will be put up immediately and work begun at once on the smelter.

PINAL COUNTY.

SILVER KING.—Mr. R. W. Phillips has resigned, and Mr. Arthur Macy has been appointed superintendent.

WINDSOR.—Work has been stopped for some unknown reason.

YAVAPAI COUNTY.

ARIZONA QUEEN.—The mines are rapidly opening up. The work on the Chicago mine, owned by this company, is prosecuted night and day, and a new body of good ore for stoping is rapidly developing.

SENATOR.—The old mill is to be started up and run exclusively on custom ores.

CALIFORNIA.

EL DORADO COUNTY.

MORRELL CONSOLIDATED.—This mine adjoins to the once famous Cedarberg. Present developments indicate that the owners have in their property a well-defined ledge rich in gold-bearing rock. The mine has a six-stamp mill. A 120-foot tunnel, now run, shows some very rich gold-bearing quartz. Another tunnel, designed to tap the lode at a depth of 50 feet, is running. The tunnel will give a sufficient test as to the value of the mine. The ledge and ledge matter are two feet thick, and are said to be rich.

FRESNO COUNTY.

A description given of the resources of this county states that many discoveries of late years show much free gold and only await the coming of capital and labor to prove very remunerative. During the last decade, the mining interests of this section have greatly revived under the stimulus of important developments in a number of quartz ledges. Extending from Dry Creek north a distance of about sixty miles, is a country containing large and well-defined quartz veins. Some have been thoroughly prospected and assays have shown the presence of either gold, silver, copper, or iron—in many instances, in paying quantities.

PLUMAS COUNTY—GREENVILLE DISTRICT.

ARCADIAN.—For some months past, a tunnel has been run to explore the ledge at a greater depth. The ledge has been reached, a drift started, and an ore-body opened up that is much superior to any found in the upper tunnels. No great amount of ore has yet been taken out. A succession of tunnels has been run, to test the ledge at different depths.

CHEROKEE.—The mine is in charge of George Standart, and he has a few men at work drifting.

MICHIGAN HILL.—Operations have been resumed.

PLUMAS-EUREKA.—An agreement has been entered into between this company and the owners of the Halstead mine at Rich Gulch, by which the former is to finish a tunnel already partly made, to prospect the ledge. If the company is satisfied with the prospect, it is to have the entire claim of 6000 feet by paying to the present owners $60,000. Work will at once begin.

SANTA CLARA COUNTY.

QUICKSILVER MINING COMPANY.—A dispatch to the New York *Tribune* says that a suit involving $20,000,000 was begun at San Francisco, November 20th, the widow and heirs of John Bowie Gray bringing suit against the Quicksilver Mining Company, of New Almaden. Gray, who was one of the three original proprietors of the mine, died in New York in 1861. The action is based upon the alleged fraudulent administration of the property by Robert J. Walker, formerly Secretary of the Treasury, who had been a partner of Gray, and was until recently the chief representative of the company.

SIERRA COUNTY.

It is reported that very extensive mining operations will begin at once on the Gibsonville and La Porte Ridge, and in the Sawpit country, under the general management of Mr. J. H. Thomas, backed by English capitalists. The company is prepared to expend a large sum of money in developments.

GRIZZLY.—This ledge, which is near the Alaska mine at Pike City, is now reopening by direction of the present owner, M. l'Anson, of Newark, New Jersey. The Grizzly ledge was originally located in 1854 by some miners, who found rich gold quartz in the croppings. At various times since, the ledge has yielded rich specimen quartz, but the vein is a milling ore, carrying fine free gold and sulphurets. A working adit is driving from Texas Ravine that will tap the lode at a considerable depth below the present workings.

CANADA.

NEW BRUNSWICK.

Work on the Dorchester copper mines is progressing. About fifty men are employed.

BELLIVEAU ALBERTITE AND OIL COMPANY.—The diamond drill, at the depth of 650 feet, passed into oil shale, and soon oil in considerable quantities came up with the water used in working the drill, and has continued to flow to a more or less extent to the present time. Since striking the oil, the drill has passed through 100 feet of this oil shale, and now, at the depth of 750 feet, where they are operating, this shale has become very soft, and a larger flow of oil came up than at any one time before. Some of this oil shale is so thoroughly impregnated with oil that, after being brought up and exposed to atmospheric action, quite large globules of pure oil ooze out on its surface.

COLORADO.

BOULDER COUNTY.

DIRIGO TUNNEL.—Work is steadily progressing, the tunnel having already penetrated the mountain 600 feet, intersecting a number of large veins of low-grade ore. The company proposes to continue work steadily until the Yellow Pine vein is reached. The tunnel intersects the New Enterprise and the western extension of the Williamson group. The company owns twenty-two claims on the line of the tunnel.

CHAFFEE COUNTY.

COLUMBUS.—It is stated that the mill will close down for the winter. Operations on the mine will, however, continue during the season.

GILPIN COUNTY.

CALIFORNIA.—The company now employs 30 stamps of its 50-stamp mill in Black Hawk, as also the full capacity of the Hidden Treasure 50-stamp mill on ore from that mine, making a total of 80 stamps now employed. In the California mill proper, there is attached to two five-stamp batteries a Frue vanner, the slimes from the batteries being deposited in a receptacle and thence elevated and treated on the Frue vanner. So far, it has proved very successful, and quite a saving over manual labor.

HINSDALE COUNTY.

ILLINOIS BOY.—This mine has been sold to the White Cross Mining and Milling Company. The mine will be worked at once.

LAKE COUNTY.

AMIE.—The company and lessees are both working, and nearly every shaft on the claim is operated.

CHRYSOLITE.—The shipments of iron ore by lessees have been suspended. The Marden lease on the Chrysolite mine, embracing the northwestern portion of the mine's old workings, has recently disclosed some very high-grade ore, and mineral in considerable quantity is hoisted daily that is literally covered with chloride of silver.

CUMMINGS & FINN.—These works will hereafter be known as the Fryer Hill smelter.

DAISY CONSOLIDATED.—The tramway, about 1200 feet long, running from the mouth of the Daisy tunnel proper down the steep mountain side to the ore-bins in the valley is almost completed. The Daisy tunnel shows ore-bodies that run from 80 to 300 ounces. The ore has an iron base, and carries about twenty per cent in lead. Work in the Elk tunnel of the consolidation has been postponed, owing to the fact that there is no way of taking care of the ore at the present time, nor will there be, perhaps, before spring. The ore in this tunnel is not as high-grade as that of the Daisy, but it shows a higher grade in each week's development. In excavating for the foundation for the hotel, a body of mineral has been exposed which has proved the richest and most extensive of any in the consolidation. It is an eight-foot vein of sulphurets, which runs about 300 ounces in silver and carries thirty-six per cent in lead. The vein has been cut in several places, and shows itself to be a true fissure, from which a large quantity of ore has been taken. Just above and to the left of this unexpected discovery, is another vein of high-grade ore which shows a large body of mineral, the extent of which is not at present known. Drifts, tunnels, and shafts have been made in this body, but as yet the walls are undefined.

LITTLE CHIEF.—The company is continuing to work in the northern end of the claim, securing some fair ore, but no new developments are reported. The sinking of the south or No. 9 shaft is also continued, and the dump shows some fair-looking contact matter, but no ore has so far been encountered.

MATCHLESS.—Operations continue without change, and a regular production is maintained. The exploration-drifts to the north and northeast of the north shaft, for a hundred feet past in seventeen-ounce siliceous ore, have lately penetrated a material carrying more iron, and the outlook for profitable ore-bodies to the north has greatly improved.

ROBERT E. LEE.—The drying and sampling-mill is kept employed continually on the ore hoisted daily from the mine. In addition to these shipments, the mine is shipping between 200 and 300 tons daily of second-class material from the dumps, accumulated during the past year. This material is sent both to stamp-mills and smelters. The dumps, before shipments were begun, contained from 12,000 to 15,000 tons of ore, estimated to contain from 15 to 30 ounces in silver to the ton.

SILVER CORD.—It is reported that the mine shut down November 15th. This is owing to the low price of lead, which greatly affects the ore of the character produced by the Silver Cord, and a disagreement with the smelters, which prevents the ore from being marketed to the best advantage. The company has decided to suspend its output until operations can be conducted more profitably

OURAY COUNTY.

CIMMARON.—The owners of this mine recently met the leading members of the Miners' Union, and proposed a compromise, agreeing to pay $2.75 per day and board. The union called a meeting and considered the matter, agreeing to accept the sum stated, provided the mine would reinstate the strikers. They also demanded other concessions. Twenty-five men went to work on the mines at from $2.50 and board up, and went to work armed. They apprehend another invasion from the strikers.

PARK COUNTY.

CHICAGO SAMPLING AND CONCENTRATING COMPANY.—This company, having purchased the Park County Sampling and Concentrating Works, located at London Junction, and having repaired the same, is now prepared to purchase good concentrating ores for cash.

SUMMIT COUNTY.

A number of mines on Gibson Hill, near Breckenridge, are working under leases and producing regularly. The Mayflower mine, in the same vicinity, is also shipping. The Gibson Hill Mining Company is working fifteen men and shipping from thirty to forty tons of ore a week. The Warrior's Mark mine, nine miles below Breckenridge, worked on a lease, is sending ore to Denver regularly. The mine looks better than ever before. The Brittle Silver Company's mill at Decatur has been started up. The Cashier mine, on Teller Mountain, in the Hall Valley District, was sold recently to an English company. The Little Chicago Mining Company has just let another contract for three hundred feet of work on its property on Sheep Mountain.

ROBINSON CONSOLIDATED.—The mine is again shipping about three cars of ore a day.

DAKOTA.

FATHER DE SMET.—The superintendent writes November 4th: I herewith inclose express company's receipt for bar No. 170, containing 1049·95 ounces of gold, the result of clean-up of mill for last half of October, making a total of 1798·65 ounces for the month. At the mine, the outlook remains about the same, no material changes having taken place to speak of. We have stopped work in Golden Gate south header, for the present, and will confine the work to opening out in ledge for a chamber, the header being far enough advanced for all purposes now. The east cross-cut, third level, has not developed any thing of much value as yet, but I feel hopeful of finding a better quality of ore in there soon. The mill is running well.

IDAHO.

MCNUTT.—This mine is on Moose Creek, in Lemhi County, and consists of a gravel bar, which is something like half a mile wide by two and a half miles in length, and embracing something more than 800 acres. This bar is twelve feet deep where it is now worked, and increases in depth as it goes up-stream. The

Digitized by Google

upper hole, where sunk to the bed-rock, is twenty-three feet deep. The deposit contains no large rocks; every thing is run off by the current through the sluices. The washing is done by two Little Giants. The ground has been thoroughly tested over the whole extent, and this prospecting has been going on for ten years past. The gold averages from 930 to 941 fine, and brings $19 per ounce. The cost of machinery and improvements up to this time exceeds $100,000. At present, the washing season lasts only through the spring and summer months; but there is ample opportunity to increase the supply of water by new reservoirs to twenty times the present amount. The cost of such a reservoir is estimated at $20,000, ample material for the same being convenient.

MAINE.

SULLIVAN.—The company is making arrangements to prospect its mine with a diamond drill.

WEST LUBEC SILVER.—This company has temporarily suspended operations in the shaft, and is preparing to lay the foundations for heavy machinery, which will be put in running order this winter.

MEXICO.

A correspondent of the Mexican *Financier* writes from Zacatecas that mining industry there, already very lively, will be given a great boom by the coming of the Mexican Central Railroad; for the mines can be much more profitably carried on than by the slovenly methods now in vogue. The difficulty in the way of working the mines has been, not only the lack of improved machinery, but also the lack of fuel for running the machinery after it had been brought here. Therefore, however much inclined to adopt progressive methods the owners of mines might be, the patio process has been clung to out of necessity.

A great deal of American machinery will be put in here when the railroad is finished; for then the road will settle the fuel problem, bringing coal down from the north at rates which will enable the profitable working of the mines under modern processes. There has already been some American machinery put in here lately, but it has been at a great expense.

There are something like 150 mines in this district, and the output last year was $6,000,000 in silver. The profit, under the expensive patio process, is much curtailed as compared with modern methods, and from the rich character of the ore it may be anticipated that there will be a great demand for American machinery as soon as it is attainable.

The ore is chiefly black sulphurets. Gold is so seldom encountered that it is hardly worth while reckoning it as a product here. Virgin silver is very common in the ore. The ore grows richer as it goes down, but 1200 feet is about the greatest depth that has been attained, owing to the difficulty of pumping by the crude prevailing methods, and on this account many mines have been abandoned at a much less depth than that. Some mines here now yield very high, but the average is about 75 ounces.

MICHIGAN.

The men at the Ludington mine joined the Chapin mine strikers at Iron Mountain November 17th, and, with a brass band, paraded the streets from 800 to 1000 strong. Four hundred of them then surrounded Superintendent Stockbridge, of the Ludington mine, and, upon his refusal to yield to their demands, attacked, kicked, and beat him until he promised them any thing they wanted. The mob then started in search of Superintendent Cody, of the Chapin mine, but he had started for Milwaukee. The men threaten that, unless their demands are conceded, they will compel the stoppage of the pumps at the Chapin mines, and allow them to be flooded. Later reports have not yet been received.

A dispatch to the Boston *Herald* states that the shipments of iron ore from the Menominee and Marquette districts during the week ended November 19th show a still further falling off, compared with the same time last year. The shipments for the week from four lake ports aggregate only a trifle over 38,000 tons, against over 68,000 tons last year, a decrease of about 30,000 tons. The total for the year is very much less than for 1882. The record for this season to date is as follows: Escanaba, for both Marquette and Menominee districts, 1,385,080 tons; Marquette, 682,523 tons; l'Anse, 64,804 tons; and St. Ignace, 55,851 tons—the last three ports shipping for the Marquette District; total, 2,188,313 tons. The total for 1882 to this date was 2,751,226 tons, showing a decrease this season thus far of 562,913 tons. Earlier in the season, it was predicted by many that shipments would increase as the year advanced, and the most sanguine prophets estimated that the total shipments would equal those of last year; but the rate of decrease has grown greater as the season advanced, and the falling off now is greater than at any time before. The extremely cold weather last week led to the belief that the season would close early, and on all sides active work is almost at a stand-still. In most mines, only a small force of men is now employed. At many mines, the work of forwarding ore has ceased for the year. The largest amount shipped from any one mine during the year has been from the Chapin, the output from that mine being over 262,000 tons to date. Next come the Republic, Lake Superior, Champion, and Cleveland, in the order named. Chapin, however, shows a record far ahead of any other. The output of the Republic is about 151,500 tons. The superiority of Chapin's business is believed to rest largely in the fact that the royalty paid there is only 40 per cent, while the average of other mines is over 50 per cent, in some cases being as high as 65 and 70 per cent. At the royalty paid the owner in fee of Chapin, even at the comparatively low rate quoted, the amount so paid will be $108,000 for the season, placing Chapin's output at 270,000 gross tons, which it will probably be. This question of royalties will play an important part in the calculations of operations for the coming year, especially if the present depression in the iron trade continues.

ASHLAND MINING AND EXPLORING COMPANY.—This newly organized company has been at work for several weeks on section 27, town 47, range 47. Ore was recently struck, and a shaft has been sunk to a depth of 10 feet in clean blue hematite of most excellent quality. The extent of the vein has not yet been fully determined.

IRON HILL.—It is stated that work will be resumed soon.

MAY.—A pump and boiler will be placed on this company's property, when explorations will be pushed vigorously. Several test pits put down on the tract show a fair quality of hematite ore. A shaft some 20 feet in depth has been sunk.

PEWABIC.—Developments are watched with interest, owing to a slight improvement underground in the mine.

SAGINAW.—This company has a diamond drill exploring its property adjacent to the Perkins mine. Nothing of value has yet been reached.

VULCAN.—Only a small force of men is now employed. During the winter, the mine will be put in shape for rapid and economical production.

MONTANA.

DEER LODGE COUNTY.

GRANITE MOUNTAIN—On the 31st of October, the company shipped 72 bars of bullion, valued at $157,573. This was the product of 1434 tons of ore. As this was worked in a leased mill, it may be that the company will not be able to have any more milled for several months.

MEAGHER COUNTY.

CLENDENNIN MINING AND SMELTING COMPANY.—One furnace is at work, turning out daily from 150 to 175 bars of silver bullion, mostly from the Silver Bell mine.

MAGINNIS.—The amount of ore worked in October from the Hauser and Holter mines was 330 tons; amount of gold saved, 493 ounces; net value, $8756.75. The average assay value of tailings is $61 in gold and seven ounces in silver per ton—total value in 330 tons, $31,190. Total expense for mining and milling, $4.06 per ton. Owing to the great loss in tailings, the mill has been closed down with the intention of introducing pans in the spring.

SILVER BOW COUNTY.

MOUNTAIN VIEW.—It is said that this mine is an extension of the Anaconda. A shaft has been sunk 500 feet deep, and a fine grade of copper ore in the south 300-foot cross-cut has been struck. A north vein has also been intersected, and with a little more exploration, the extraction of ore on a large and profitable scale will begin.

NEVADA.

ELKO COUNTY.

BELMONT.—Winze No. 1, 55 feet north of face, is down 25 feet and yielding splendid black metal and chlorides. All stopes in south tunnel and Laity ground are yielding first-class ore, some of which assays very high; the mill is doing splendid work; chlorinations average 91 per cent.

GRAND PRIZE.—The mill has started and is working well. Pulp assays, so far, have averaged $224 per ton.

NAVAJO.—The mill is ready to start as soon as work of the drain-pipe through the North Belle Isle is completed.

EUREKA COUNTY.

MERRIFIELD.—This mine, after producing heavily for several years, was closed down last August, and has passed into the control of a New York corporation. All claims against the old management have been settled in full.

STOREY COUNTY.

The following is the report of County Assessor, showing the proceeds of the mines of this county, as they appear on the assessment-roll for the quarter ended September 30th, 1883:

Mine or company.	Ore extracted. Tons.	Value per ton.	Gross value or yield.	Total cost.	Net yield.
Belcher	1,400	$20.00	$29,150.11	$26,828.45	$5,830.02
Crown Point	3,985	13.00	55,309.33	53,511.19	11,061.86
Challenge	374	13.00	5,161.20	7,106.00	1,032.24
Consolidated Imperial	123	13.00	1,704.30	2,346.50	340.86
Kentuck	2,569	22.00	58,018.69	48,811.00	11,603.73
Ophir	773	16.00	12,063.44	27,637.72	2,412.68
Potosi	2,597	12.14	31,552.06	30,253.64	6,310.40
Yellow Jacket	3,325	14.00	46,983.64	75,900.35	9,396.72
					$47,968.52
Lady Bryan	143	$7.00	$1,001.00	$1,072.50	$100.10
Monte Cristo	319	12.69	4,048.31	4,048.31	809.66
Lady Bryan	600	5.00	3,000.00	2,850.00	300.00
					$1,209.76
B. Pfeifer's tailings mill	369	$2.00	$738.00	$738.00	$73.80

ALPHA AND EXCHEQUER.—The work at these mines is prosecuted very economically. During the month of October, the total expense of the two mines was $3400, including wages, salaries, and supplies. The joint west drift from the Imperial shaft on the 600 level has been extended a total distance of 150 feet. It will be run to the west wall, and is expected to cut through a promising body of quartz in its progress.

BEST & BELCHER AND CURRY.—A change of material has occurred in the joint Best & Belcher and Curry winze, below the 2550 level. It is a black, decomposed matter, which looks like slag from a furnace, and contains much base metal, principally iron. They are putting in machinery at the Banner shaft preparatory to resuming work on the 1200 in the Gould & Curry, and are now at work in four different places in Curry.

NEW HAMPSHIRE.

WARREN.—A number of experiments are making in smelting the ore by the vapor fuel process. The ore runs from 35 to 40 per cent zinc, 8 to 10 ounces silver, shows a trace of gold, 11 per cent lead, and about 35 per cent of sulphur. The vein is a true fissure, and is from 4 to 30 feet thick, and has been traced upon the property for a distance of more than 6000 feet. Some 8000 tons of ore are in sight. Two shafts have been sunk, and every thing is in readiness for taking out the ore. A large amount of private capital has been used in putting the property upon its present paying basis.

NEW MEXICO.

GRANT COUNTY.

BONNIE JEAN.—The shaft is down 273 feet and the outlook is very favorable. Sixty-five feet of cross-cutting at the 200-foot level shows up four distinct veins or spurs, running in copper, silver, and gold to the value of $61 per ton. This was above the water-level, which was struck at the depth of 270 feet. A fifty horse-power engine, with hoisting machinery complete, has been purchased and shipped to Shakspeare.

IVANHOE.—The reverberatory furnace has blown in lately and is running satisfactorily. There is enough ore on hand to keep the furnace running all winter. However, a force of men will be kept at work on the mine, taking out ore to fill the contract with the Deming smelter.

CINCINNATI.—This mine has a good pay-streak of silver ore, from which it is taking out about two car-loads per week and shipping to Pueblo and receiving profitable returns.

UTAH.

EMERY COUNTY.

The ore of this new mining district near Cedar Mountain is said to be found in sandstone similar to that of Silver Reef. Ore is said to be abundant, and wood and water plentiful. The country is reported mild and excellent for winter work.

SALT LAKE COUNTY.

TRUE FISSURE.—At this mine, a large body of ore is developing with satisfactory results.

VALLEJO.—The recent strike in this mine is the largest made in Alta for several years past. The ore assays 130 ounces silver, and there are about 200 tons ready for shipment.

SUMMIT COUNTY.

CRESCENT.—At the recent meeting, the following directors were elected: President, E. P. Ferry; Vice-President, J. J. Daly; Treasurer, W. S. McCornick; Secretary, C. H. Withey. The report presented shows receipts from ore sales $348,000. Expenditures: Dividends, $150,000; purchase of Walker & Webster, $50,000; permanent improvements and property on hand, $148,000; total, $348,000. The "property on hand" item includes supplies for the mine sufficient to last until July 1st, 1884.

ONTARIO.—The shaft at the No. 3 has reached a depth of 855 feet, and the work of cutting the stations is to be commenced at once. Burleigh drills are to be used to hurry forward the work. These stations are deeper by about twenty feet than the 800 in No. 2, and when completed a tunnel will be run to carry the water from No. 2 to the tank station of No. 3, from which place it will be thrown to the 600 tunnel by the Cornish pumping-engine. Ore is mined at the 900 station of No. 3, and shipped to the mill. At No. 2, preparations are carried forward to cut the vein at the 900 level, which will be 100 feet deeper than the lowest workings in the mine at the present time. It is calculated that the cross-cut from this station will cut the vein in about sixty feet.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Nov. 23.

Business was better and more generally distributed in the mining market this week, and especially was this noticeable in the dividend-paying stocks. Chrysolite formed the chief interest in the market, and was very actively dealt in. It was quite strong at one time, but declined to-day. It is the belief that the advance is to create a "short" interest, as there are no new important developments from the mine. Green Mountain developed considerable strength under moderate dealings. The reports from this property seem to be favorable. Some of the low-priced or fancy stocks foot up a large total in dealings, but they suffered no material change in price. A full summary of the market is given below. The total number of shares sold aggregates 181,788, as against 121,565 last year.

The Comstock shares were very quiet at steady prices. California sold at 25c. Consolidated Virginia was irregular, under a fair business, selling from 45@39@40c. Sierra Nevada was quiet and steady at $3.25. Union Consolidated was weak, declining from $3.70@$3.10 under a small business. Mexican was strong, selling from $2.65 $3@$2.80. Ophir sold at $6. Sutro Tunnel was moderately dealt in at steady prices; it sold from 14@16@15c.

The Leadville stocks were quite strong, and were very actively dealt in. Amie was active and steady, selling from 14@13c. Chrysolite was quite strong under a very active business; it sold from $1.30@$1.70@$1.45. There has been no rich and important strike made in the Marsden shaft, as was currently reported, and an officer of the company states that there have been no new developments made in the mine. Dunkin was quiet at 20c., and Breece sold at 14c. Iron Silver was actively dealt in at irregular prices, selling from $2.40@$2.30. The bullion product from this mine for the month of October amounted to $110,000, and the profit for the month, $21,000. The company states that it will pay its usual dividend next month although the showing for October is not so good as the preceding month. They state, however, that they have ample funds on hand for that purpose. Leadville was weak, under a small business, selling from 55@45c. Little Chief was steady under small transactions, selling from 54@58@55c. Little Pittsburg was quiet and irregular, selling from 55@50@51c. Climax sold from 6@9c., and was actively dealt in.

The Bodie stocks were quiet and steady. Bodie Consolidated sold at 50c. Standard was quiet and steady, selling from $6.25@$6.50@$6.38. Bulwer was weak, under a small business, selling from 49@40c. North Standard sold at 13c.

The Tuscarora stocks were moderately dealt in at steady prices. Grand Prize sold from 33@30c. Belle Isle was quiet and steady at 34@30c. Navajo sold at $4 under a small business. North Belle Isle was quiet and steady, selling from 55@50c. Independence sold at 20c. Elko Consolidated was steady under a small business, selling from 19@18c.

In the miscellaneous list, Eureka Consolidated was irregular, selling from $4@$3.50@$3.75 under a small business. Green Mountain was quite strong, under a small business, selling from $1@$1.20; it is reported that the advance in this stock is owing to reports from the mine that the tunnel is making a progress of eight feet a day, and is rapidly nearing the famous Blake chute. It is also said that the company made a small profit last month. Homestake sold from $9@$8.75@$10, with small transactions. Horn-Silver was strong, under a fair business, selling from $6@$6.63@$6.50. Ontario was weak, selling from $30@$29; the transactions were small. Robinson Consolidated was quiet and weak, selling from 41@36c. Sierra Grande was also weak, under a small business, selling from $1.10@90c. Silver King was strong at $7.

Barcelona was quiet and steady, selling from 22@25c. Caledonia showed a little weakness, declining from 25@20c. under a small business. Central Arizona was quiet and steady, selling from 17@24c. Decatur sold at 5c., with a very active business. Eastern Oregon was very active at steady prices; it sold from 43@45c. Harlem was strong, under a small business, selling from 99c.@$1.10. Lacrosse was considerably dealt in at weak prices, selling from 10@7c. Oriental & Miller was quiet, and sold from 2@6c. Red Elephant sold at 6c. under a small business. Sonora Consolidated was very actively dealt in at steady prices; it sold from 28@25c. North Mexican was listed on the Exchange this week, and was quite strong at 65c. at one time; it declined to-day, however, to 30c., but reacted and closed at 55c. The property of this company is situated in the Magdalena District, Sonora, Mexico, and consists of three developed mines and a two-stamp mill. The company proposes to add six more stamps, which are now on the way to the mines. It is said that the company has expended about $45,000 in developing the property alone. The mines are within ten miles of the Sonora Railroad.

The New York Mining Stock and National Petroleum Exchange and the Exchange for Unlisted Securities have consolidated, the members of the latter Exchange paying $200 for membership in addition to $40 *pro rata* on life insurance fund.

DIVIDENDS.

The Ontario Silver Mining Company, of Utah, has reached the eighty-ninth dividend ($75,000 for October), and aggregating a total paid of $5,075,000. The present dividend is payable at the office of transfer-agents, Lounsbery & Haggin, No. 15 Broad street, on November 30th. Transfers close on the 24th.

The Plumas-Eureka Gold Mining Company, of California, paid a dividend of 50 cents a share, in London, on the 12th ult., aggregating $20,312.50. Total of dividends this year, $40,625.

The Sierra Buttes Gold Mining Company, of California, paid a dividend in London on the 12th ult., of 25 cents a share, aggregating $5625. Total of dividends this year, $11,250.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway, report as follows for the week:

The advance in prices two weeks ago from $1.10@$1.19 has been pretty well sustained, the lowest price on the reaction being $1.15¾. On Thursday, amid great excitement, the price was advanced from $1.17⅝, the opening, to $1.19⅞ in New York, and $1.20 in Oil City.

The range of fluctuations during the week has thus been from $1.15¾@$1.19⅞. To-day (Friday) the opening was $1.19⅛, but the market shaded off to $1.18¼, but rallied a little and closed at $1.18¾.

The general tone is decidedly bullish on the decreasing stocks of oil and diminishing production. The bulls freely predict $1.25@$1.30 oil, and claim that the Standard is inclined to advance Refined, which is now 9c., strongly bid, and that it will exercise a very bullish influence on crude; that if, last fall a year ago, prices were put to $1.36, and the past summer to $1.24½, the situation now warrants still higher prices.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Nov. 17	$1.17	$1.17⅝	$1.16⅝	$1.17	6,619,000
19	1.17	1.17	1.15¾	1.15⅞	7,226,000
20	1.15¾	1.18¼	1.15¾	1.18⅛	6,645,000
21	1.18¼	1.19	1.17¼	1.17⅝	8,132,000
22	1.17⅝	1.19¼	1.17⅝	1.19¼	8,697,000
23	1.19⅛	1.19¼	1.18⅛	1.18¾	6,219,000
Total sales					43,808,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, Nov. 22, 1883.

The market for copper stocks the past week has ruled extremely dull, but at the same time there is a good degree of firmness to prices, which gives encouragement for a better time coming. There are but few stocks offered for sale at present prices, and, should an active demand set in, we look for a considerable advance, especially on the dividend-paying shares. Calumet & Hecla dropped one point on the early dealings to $237, but quickly recovered and is now steady and in good demand at $238. Franklin advanced from $11⅛@$11¾ on sales of 50 shares. A dividend of $2 per share is talked of as probable some time next month. Quincy sold at $52, same as last week. Atlantic sold at $10; last sale $10¼, September 11th. Nothing doing in the rest of the list.

In silver stocks, there is a firmer tone, and better demand for good stocks. Catalpa advanced from 30@37½c. Crescent sold at 20c. Bowman Silver has been active, and, on good reports from the mine, advanced from 11@20c., with a reaction to 17c. The stock is well held, and higher prices are predicted. Massachusetts & New Mexico sold at 2c. Dunkin, sales at 26@28c., same as last week. Sullivan sold at 94c., closing 90c. bid.

3 P.M.—There was no material change in the market this afternoon. Prices continue firm. Sullivan sold at $⅞. Catalpa, $⅝ bid. Calumet & Hecla, $238; sales closing $237 bid, $239 asked. Quincy, $50 bid, $52 asked. Pewabic, $3½ bid, $4 asked. Atlantic, offered at $11 Osceola, offered at $19, no bid. Silver Islet, $3 bid, $4 asked.

BULLION MARKET.

NEW YORK, Friday Evening, Nov. 23.

As foreshadowed in our last week's postings, the silver market has declined, and may be reported as still weak under the lower rates of exchange on India, and is likely to recede still farther.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
Nov. 17	50 11-16	110⅝	Nov. 21	50½	110

20	50⅝	110¼	23	50½	110

* 110¼@110⅜.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended November 23d, as compiled from various sources, amounted to $161,000, as against $257,000 reported for the previous week. The receipts from January 1st, 1883, to date are $10,316,443.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended November 17th	$30,750
Corresponding week last year	54,400
Since January 1st, 1883	12,980,109
Corresponding period last year	44,668,621

Imports.

Week ended November 17th	$1,442,751
Corresponding week last year	457,166
Since January 1st, 1883	18,900,413
Corresponding period last year	5,485,335

Foreign Bank Statements.—The governors of the Bank of England, at their weekly meeting, made no change in the bank's minimum rate for discount, and it remains at three per cent. During the week, the bank lost £21,000 bullion, but its proportion of reserve to its liabilities was unchanged at 42¼ per cent, against 40⅝ per cent at this date last year. November 22d, the bank lost $193,000 bullion on balance. The weekly statement of the Bank of France shows an increase of 525,000 francs in gold and a loss of 1,475,000 francs in silver.

Digitized by Google

Silver for Dimes.—A special purchase of 50,000 ounces of silver bullion has been made by the Treasury Department. It is to be used in coining a sufficient number of dimes to supply an unusual demand for that coin on the Philadelphia Mint.

METALS.

NEW YORK, Friday Evening, Nov. 23.

Copper.—The market has been very quiet during the week. The Lake companies are not sellers, there is very little copper offering by outsiders, and the demand is moderate. We quote nominally 15c. for Lake, and 14⅛@14¾c., according to brand, for other kinds. The latest cable for Chili Bars is £59 7s. 6d.

The following are the Board of Trade returns, just received, for the first ten months of the current year, the figures printed last week having been for the first nine months:

	Jan. 1 to Oct. 31. 1883.	1882.
	Tons.	Tons.
Imports:		
Pure in pyrites	12,814	13,161
precipitate	18,465	14,706
ore	13,444	13,045
regulus	7,823	7,193
Bars, cakes, etc.	29,698	29,510
	82,244	77,615
Exports:		
Raw (English)	14,000	10,525
Sheets	12,965	13,569
Yellow metal at 60 per cent	10,008	9,285
Brass at 70 per cent	2,842	2,825
	39,815	36,204
Foreign	9,633	10,814
	49,448	47,018

Tin.—Under a good deal of trading, this metal has weakened further, and is now quoted 19¼c. for spot Straits, cash. This afternoon, London broke to £86 10s. for spot, according to a dispatch received at the Metal Exchange.

Lead.—In the middle of the week, the agent of one of the Western refiners took 1000 tons of Pueblo at 3·70c., and since then a few hundred tons have been sold at that figure. Buyers are too much frightened at the recent rapid decline to show any confidence in the metal, so that some of them who might be induced to take hold if they considered the metal low are holding off, and it would probably be difficult even to place any round lots at more than 3·65c. for Common, so far as the manufacturing trade is concerned. We are approaching a dull season, and there is not much encouragement in the early future for the metal.

Messrs. John Wahl & Co., of St. Louis, wire us as follows to-day:

The price is declining, there being more sellers than buyers in the market. Sales during the week foot up to 150 tons of Refined at 3·60c., and 300 tons of ordinary Missouri at 3.50c. Refined will not bring over 3·50c. now.

Messrs. Everett & Post, of Chicago, telegraph us to-day:

Our market has declined slowly since our last report on sales of 110 tons at 3·45c. It closed somewhat better, with sales of 500 tons at 3·47½c.; and though some sellers still ask 3·45c., buyers are shy about anticipating their wants.

Spelter.—There is nothing new to report. Common Western is dull at nominally 4⅝@4½c., with Silesian at 5½c. asked.

Antimony.—This metal is stiffer to-day. We quote at the close, 9¾c. for Hallett's and 10½c. for Cookson's.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Nov. 23.

The following figures, taken from the report of the British Board of Trade, show the exports of iron and steel from Great Britain to this country during the first ten months of this and preceding years:

	1881.	1882.	1883.
Pig-iron	347,242	422,863	245,742
Old iron for remanufacture	74,594	77,002	41,576
Steel unwrought	103,350	122,453	28,471
Tin plates	146,611	182,815	184,251
Hoops and sheets	30,753	31,875	27,538
Bar, angle, bolt, and rod	11,521	18,076	8,064

American Pig.—We print elsewhere an abstract of Mr. Swank's statistics of stock and of the condition of the furnaces, which is encouraging as far as it goes. Briefly, it shows that stocks have fallen off a little, and that the number of furnaces in blast is less. On the other hand, it must not be forgotten that from July to November is the busiest part of the year in many branches, and that though the demand was disappointingly small this year, it is likely to be still less during the next months. This explains the apathy of buyers, and should not be forgotten by producers, or cause any undue rejoicing over Mr. Swank's figures. They will not do for a "bull" argument, but, on the other hand, they do not leave any opening for a "bear" attack. The market for Foundry irons is quiet and dull. We quote Foundry No. 1, $20@$22.50; No. 2, $18.50@$19; and Gray Forge, $17@$18.50, all at tide-water. There has been some business in Bessemer Pig, which we quote $20 @$20.50. Spiegel is quiet at $30.50@$31.

At the Exchange, the following transactions were reported during the week: Saturday, 100 tons No. 1, December, $20; Monday, 100 tons No. 1, March, $20.50; Tuesday, 200 tons No. 1, February, $20.50; 200 do., March, $20.50; 200 do., April, $20.50; Wednesday, 100 tons American Pig, No. 1, March, $20.50; Thursday, 100 tons No. 1, December, $20; 500 do., March, $20.50; 100 do., April, $20.50; 200 do., February, $20.50; 200 do., March, $20.50; 200 do., April, $20⅝; 200 do., May, $20⅝.

Scotch Pig.—The market is dull and depressed, and in spite of the fact that arrivals are moderate, some of the iron goes into store.

We quote ex ship and to arrive: Coltness, $23; Langloan, $23@$23.25; Summerlee, $22.50@$23; Eglinton, $20@$21; Glengarnock, $21.75@$22; Dalmellington, $20@$21.

At the Exchange, the following cable quotations were received to-day: Coltness, 55s.; Langloan, 55s.; Summerlee, 54s. 6d.; Gartsherrie, 52s. 6d.; Glengarnock, at Ardrossan, 52s. 6d.; and Eglinton, at Ardrossan, 46s. 6d. Warrants at the Exchange to-day were 44s. 8d.

Rails.—Business has been confined to the sale of a number of small lots, aggregating probably between 15,000 and 20,000 tons, varying according to time and locality of delivery between $35 and $36.

Old Rails.—Business has been dull. We quote $22.50@$23.

Philadelphia. November 23.

Pig-Iron.—Since Monday morning, a large amount of Gray Forge has been sold, for delivery after January 1st. The average price has been $18. Brokers and representatives of companies here are more confident this week than for two or three months, not of any improvement in price, but of a sufficient demand to absorb all stocks as produced. The decline in producing capacity has gone as far as is necessary, and the corner has been turned by the presentation of requirements which have been withheld all the fall. Forge iron has sold in 500 to 1000-ton lots, and to-day negotiations are pending for 1000-ton lots, which brokers expect to close by Saturday. The outlook is quite encouraging, as far as mill irons are concerned. Standard brands are in better request; that is to say, consumers are coming forward and paying prices which have been asked for a month past. There is still a good deal of inferior iron offered, but it is less troublesome than a few weeks ago. In short, there has been a great deal of quiet purchasing for future requirements. Nothing encouraging can be said of foundry iron. Quotations are, $20@$21 for No. 1, and $18.50@$20 for No. 2. Most of this week's business has been in 25 to 100-ton lots, at $19 and $20.50 respectively.

Foreign Irons.—Movements in foreign irons have practically ceased. Nominal quotations are $20@ $20.50 for Bessemer, and $29.50@$30.50 for Spiegeleisen. Two or three brokers have been selling a few hundred tons of Scotch at all kinds of prices. Supplies here are very light, and there is very little disposition to order for shipment.

Muck Bars.—Business in muck bars is of very small proportions. A number of contracts have been completed, and no new ones are placing. A few sales of small lots have been made at $33.50. Better makes are held at $34@$34.50.

Merchant Iron.—The local manufacturers held a meeting here on last Monday, and reduced the card rate to 2·10c. At the meeting, the opinion was expressed that trade was very dull. Few large orders are coming along; a comparatively small amount of iron is selling above 2c.; the better makes have been sold at this figure; 1·90c. has been taken for some good iron, and there are negotiations pending which will, no doubt, be taken at that price. There is still some competition from the West, and Eastern makers have no recourse but to follow it as far as they can.

Nails.—Nails have weakened, on account of the sharp competition of new mills, which are pushing their product upon the market. Jobbing demand is irregular, and there is less disposition on the part of consumers to buy far ahead, owing to the great excess of capacity. Nominal quotations, $2.80@ $2.90.

Plate and Tank Iron.—The lowest sales of Plate Iron have been at 2·25c.; 2·50c. is the nominal quotation for small lots, and there is a moderate amount of business done at that figure. Shell is nominally 3@ 3·25c.; and Flange, 4@4·25c. The demand is not very active, and consumers are providing merely for pressing requirements; but there is no great falling off in work.

Sheet-Iron.—Eastern Pennsylvania sheet-iron manufacturers report the demand for thin sheets fair, considering the season. Galvanized is less active, and, where large orders are to be had, concessions are heavier than at any time during the fall, as makers are very anxious to secure a winter's work.

Wrought Pipes and Tubes.—Quotations, 70 and 10 @75 per cent off list for gas and steam pipe, and 60 @62½ for tubes.

Structural Iron.—To-day's quotations are 2·40@ 2·50c. for Angles; 2·75@3c. for Tees; and 3·40@ 3·50c. for Beams and Channels. Prospects are favorable for the placing of orders for several thousand tons of bridge iron.

Steel Rails.—Quotations are $35 for late and $36 @$37 for early deliveries, with considerable negotiations in hand. The closing down of two mills, and the intended closing of two more, will, by the 1st of December, restrict the capacity 72 tons per turn, out of a total of 269 tons per turn, or a little over 25 per cent of the output. This will help the steel rail market materially, especially if it should be supple-

mented by one or two other suspensions which are rumored in the West. Large buyers are holding back orders in view of a further reduction in prices, which, it is thought, will follow the 10 per cent reduction in wages which has been announced in two mills, and will go into effect in all others.

Old Rails.—A few thousand tons of old rails have been ordered in 500 to 1000-ton lots, mainly American, at $23@$23.25.

Scrap-Iron.—There is a fair demand at $24@$24 50 for No. 1, and $18@$21 for No. 2.

Pittsburg. November 21.

Our leading manufacturers have been talking this week more gloomily than at any time for a year past. They have been interviewed frequently and have expressed themselves without reserve. They are of the same make, cast in the same mold. Demand is irregular, prices low. There is no inducement to continue production; consumers are holding off. Gray Forge is selling slowly at $17@$18. Very little Foundry is moving, and that at inside figures. An occasional lot of Bessemer is called for at $21, four months. Muck Bars are without any activity at $32. A restriction in the output of bar iron has been made. Several mills have come to single turn. A good many puddling-furnaces have been laid off. There is no remedy for the present state of things, excepting a heavy restriction of production. Much demand, however, is held back, which would be presented if the trade were settled. Merchant Bar is selling at from 1·75c. up. Nails, $2.50@$2.60. The five weeks' suspension will help to steady prices for a time; for the fact that producing capacity is far ahead of requirements is likely to prevent any great activity for a long time to come. Wrought pipes are 75 per cent off list. Old rails are wanted in large lots, but buyers' views are 50c.@$1 below those of sellers. Steel rail mills are well supplied with business to the last of the year, and have a few good orders for delivery next year at $35. There are numerous offers at $34@$34.50, which have not been accepted.

The window-glass strike is still unsettled. Manufacturers are resolved to fight the strike, and are importing glass to supply customers' requirements.

The oil trade is manipulated by the Standard Company, and an upward tendency is the result, but it is thought that this will result in a drop.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Nov. 23.

Anthracite.

The market for anthracite is getting into an uncomfortable shape, as some of the sizes, which until now have done fairly well, like stove, are beginning to exhibit the signs of weakness that are the result of accumulation, and the market is more now than it has been in buyers' favor. It is unfortunate that the companies do not appear to be able to reach any understanding, and it is understood that one or two of the managers insist that their plans be carried out. The main subject of difference so far as we can trace it, is that some of the companies want to repeat the old-time dodge of three days' stoppage, which means very little in the way of restriction, because the quantity brought to market is only very slightly reduced. The only thing that can be done is to stop for a week at a time, alternate weeks, and keep it up until the supply is in good shape. An announcement of such a decision would have the effect of promptly bringing out requirements now withheld.

Bituminous.

The Cumberland coal trade held a meeting at Baltimore, at which it was unanimously decided to continue the present organization, created at the time of the labor troubles.

Vessels from the Cumberland shipping ports are in better supply. Current business is small, is closely contested for, and is often taken at low figures.

Mr. John H. Jones, official accountant, has issued the following statement of anthracite coal tonnage for the month of October, 1883. This statement includes the entire production of anthracite coal, excepting that consumed by employés, and for steam and heating purposes about the mines:

	Oct., 1883.	For year 1883.	For year 1882.	Difference.
Phila. & Reading RR.....	1,328,809	8,489,686	5,626,994	I. 2,862,692
Central RR. of N. J.....	*.....	1,745,399	3,485,091	D. 1,739,692
Lehigh Valley RR.....	†675,243	5,225,464	4,840,589	I. 384,876
Del., Lack. & W. RR.....	543,515	4,218,650	3,813,712	I. 404,938
Del. & Hud. Canal Co....	‡379,478	2,910,342	2,563,220	I. 347,122
Penna. RR...	298,900	2,288,787	1,973,329	I. 315,457
Pa. Coal Co..	180,087	1,276,682	1,202,423	I. 74,259
N. Y., L. E. & W. RR	38,240	306,783	217,925	I. 88,857
Total. ...	3,426,273	26,461,793	23,723,284	I. 2,738,509

* Included in tonnage of the Philadelphia & Reading Railroad.

† This amount includes the production of the mines of the State Line & Sullivan Railroad Company, amounting to 9275 tons.

‡ In addition, there were 61,928 tons transported from the mines by the Delaware & Hudson Canal Company, during October, which are included in tonnage of other interests.

The stock of coal on hand at tide-water shipping points October 31st, 1883, was 604,865 tons; on September 29th, 1883, 538,490 tons; increase, 66,375 tons.

Buffalo. November 19.

The all-absorbing topic of the past week was the weather which prevailed for several days here and all around the lakes. The velocity of the wind varied from 25 to 60 miles an hour. Heavy snow-storms and occasionally severe frosts diversified the situation. Ice formed on Buffalo River Thursday and Friday. Probably 100 vessels have been lost on the lakes, with property worth over $500,000. The death-roll already numbers forty persons. A newspaper writer says: "It would appear that the lakes are fringed with stranded craft, which are in a more or less critical state of wreck or threatened dissolution." Vessels ashore, waterlogged, or breaking up with valuable cargoes are reported from all points (including several of our finest and largest propellers and barges). Many vessels loaded with coal have not been heard from, and grave doubts are entertained as to their safety. In fact, the storms were the most serious of any recorded for years, and the beginnings of them were unheralded in any way—a sudden change from delightful, balmy fall weather to arctic cold and blustering gales of blinding snow.

President Sloan, of the Delaware, Lackawanna & Western Railroad, is reported to have said that he has made arrangements to establish extensive coal-yards and depots at South Chicago, on the grounds and docks of the Calumet & Chicago Coal and Dock Company. Buffalo is the point whence a line of barges will start, and the road will make its own rates without the necessity of dividing with other railroad companies. If the supply of coal laid in during the summer months should not prove sufficient to fill the demand, the Delaware, Lackawana & Western can forward all the coal it needs directly to the proposed yards during the winter by any of its Western connections.

The St. Paul & Pacific Coal and Iron Company has decided to build a large coal-dock on Connor's Point about three miles from the center of Duluth. The dock will be built solid, and have a frontage of 1000 feet, with an average depth of 290 feet; the storage capacity will be 100,000 tons of coal. The end of the new dock will be 2600 feet from the end of Rice's Point, or about midway between the center of Duluth and Superior. It is proposed to have the structure ready for business by May 1st next. The estimated expense is $50,000.

Chicago. November 17.

The Delaware, Lackawanna & Western Railroad Company is about to follow the example of the Lehigh Valley Coal Company, and establish large coal-yards and distributing depots at South Chicago. These new yards will be located on the docks and grounds of the Calumet & Chicago Coal and Dock Company, from which point the Delaware & Lackawanna has excellent facilities for handling its coal business from its western terminus at Buffalo. The company will run a line of barges from the latter point, which will admit of its making its own rates from the mines to Chicago.

Horsford's Acid Phosphate,
In Seasickness.

Prof. ADOLPH OTT, New York, says: "I used it for seasickness, during an ocean passage. In most of the cases, the violent symptoms which characterize that disease yielded, and gave way to a healthful action of the functions impaired."

ONTARIO SILVER MINING COMPANY,
Mills Building, 15 Broad Street,
NEW YORK, Nov. 19, 1883.

DIVIDEND NO. 89.

The regular monthly dividend of FIFTY CENTS per share has been declared for October, payable at the office of the transfer-agents, Lounsbery & Haggin, Mills Building, 15 Broad Street, on the 30th inst.
Transfer-books close on the 24th inst.
LOUNSBERY & HAGGIN, Transfer-Agents.

MAPS.

ARIZONA AND NEW MEXICO.—This map shows all the Township Surveys, Private Land Claims, Post-Offices, and Settlements. It also exhibits the Explorations of other Government and Private Expeditions, including the facts developed by the Surveys for the Routes of Projected Railroads, etc., 1881. Scale, one inch to thirty-three miles. Colored, 24×17 inches. Pocket form, $1.

COLORADO.—Topographical and Township Map of Part of the State, exhibiting the San Juan, Gunnison, and California Mining Regions. By Louis Nell. Substantially same as above. Post-offices, March 1st 1880. Scale, 1 inch : 9 miles, 1-570,240. Plain sheets for wall, 90 cents.

COLORADO.—Cannon's Map of the Mineral Belt of Colorado. Taken from the Records of the Surveyor-General's Office, and other reliable Official Sources. Showing, in colors, the Mineral Belt, Gold Districts, Silver Districts, Coal Districts, County Lines, and Boundaries of Land Districts. There are also given the Capital, County Seats, Township Lines, Railroads, and Projected Railroads. Scale. 1 inch : 10 miles. Size, 26×30 inches. Pocket form, $1.50; as a wall-map, $2.

SAN JUAN MINING REGION (COLO.).—Kibbe's Geographical and Geological Map of the San Juan Mining Region. 1881. Shows county lines, wagon-roads, stage routes, trails, railroads, cities and towns with post-offices, camps with post-offices, reduction-works, mountain peaks, continental divide Also (by colors), eruptive rocks, Carboniferous, Cretaceous, Jura Trias. Elevations above sea-level. Scale, one half inch to the mile. 22×27 inches. Includes, on same sheet, a reduced Map of the State of Colorado. Printed in colors, with board covers. $1.50.

COLORADO.—Topographical and Township Map of the State. Compiled from U. S. Government Surveys and other authentic sources, by Louis Nell, Civil Engineer. By means of symbols, the following mass of facts is graphically shown: Railroads in operation; Railroads chartered or in progress; Wagon-roads; Wagon-roads proposed; Trails; Drainage dry during the greater part of the season; County-seats: Post-offices; Villages; Townships subdivided; Townships surveyed in outlines; Contour-lines, with vertical intervals of 1000 feet; Altitudes in feet above sea-level, by barometer observations and by spirit-levels; Private grants; Military reservations; Indian reservations ceded to the U. S. Government; Arable land, with irrigation. Tables of Areas of Counties; Astronomical Positions; Arable Land. Scale, 1 inch : 10·5 miles. Size, 31×40 inches. Pocket form. $1.50 on thick paper.

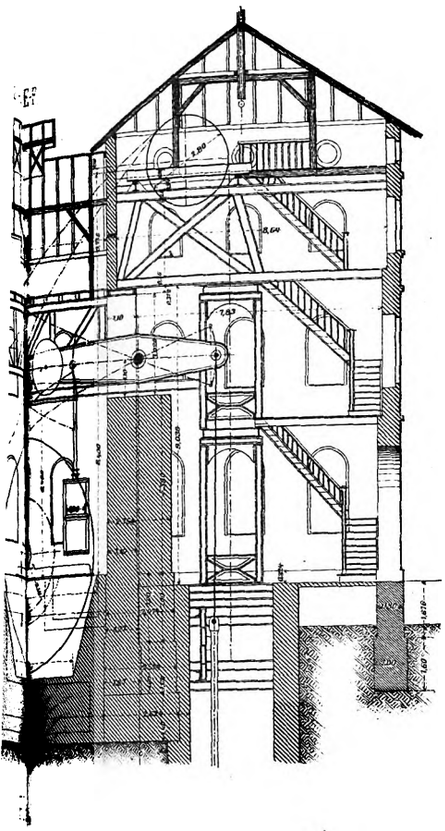
IDAHO.—The Wood River Region of Central Idaho, giving the first correct Geography of that recently explored and remarkable Belt of Discoveries of Gold and Silver Mines on the tributary streams of the WOOD and LITTLE WOOD Rivers, on the Upper Waters of the SALMON RIVER, among the SAWTOOTH MOUNTAINS, and on the Forks of the BOISE RIVER; embracing the Mount Estes and Custer Mines on the north and the Oregon Short Line Railroad on the south. Prepared by Frank J. Scott. Scale, 5 miles to the inch. Size, 15 x 26 inches. In paper pocket. Price, $1.

MEXICO.—Map of Mexico. Showing Railroads, Broad Gauge and Narrow-Gauge, Constructed; and Railroads, Broad-Gauge and Narrow-Gauge, Proposed. This very large and finely-engraved Map, constructed originally by the government for official purposes, contains all the information obtainable by it, and shows minutely the towns and villages of the entire country. Scale: 26·6 Mexican Leagues to the degree, and 69·16 English Miles to the degree; also, Kilometrical Scale. 1881. Size, 53×41 inches. Printed in colors. Pocket form, $5.

MAP OF MINING CLAIMS ADJOINING LEADVILLE, California Mining District, Lake County, Colo. By Edward Rollandet. 1879. Mounted on muslin, $2.50. In cloth-bound covers, $2.

MINING MAP OF UTAH.—Showing the location of the Mining Districts, over an extent of territory 150 miles from North to South. Compiled from U. S. Government Surveys and other authentic sources. Scale, one inch to four miles. Colored. 1879. Pocket form. $1.50.

NEW SECTIONAL AND MINERAL MAP OF UTAH.—Pocket form. Compiled from the latest U. S. Government Surveys and other authentic sources, exhibiting the Sections, Fractional Sections, Counties, Cities, Towns, Settlements, MINING DISTRICTS, Railroads, and other internal improvements. Scale, one inch to eight miles. Colored, 1878. $3.50.



POCKET MINING ATLAS OF THE MINES OF THE UNITED STATES.—Showing the Mines of NEVADA: the Comstock Lode, the Eureka, Treasure Hill, and Tuscarora Districts; CALIFORNIA, including Map of the Bodie District; COLORADO, including the Leadville, Silver Cliff, San Juan, Caribou, and Central City Districts; DAKOTA, including Map of Deadwood; MONTANA, IDAHO, UTAH, ARIZONA, NEW MEXICO, LAKE SUPERIOR REGION, the SOUTHERN STATES. 1880. Printed in colors, and bound in flexible leather covers. Price, $1.

SAN JUAN MINING REGION (COLO.).—Stockder's Map of San Juan Mining Region, compiled from U. S. Surveys and other Authentic Sources. 1881. Shows county boundaries, district boundaries, wagon-roads, trails over mountain passes from river basin to river basin, continental divide, timber-line (11,000 to 11,500 feet above sea-level), etc. Scale, 1 inch to the mile, or 1 = 63,360. 28 × 38 inches. Pocket form, stiff paper cover. $1.50; or as a wall map, $1.50.

WITHIN the past week, several severe accidents have taken place, due to the breaking down of electric light wires and subsequent discharge of the current into the bodies of men and animals who accidentally came into contact with the wire. It is likely that the recognized danger of such wires above ground will lead to an agitation to place them beneath the surface where they can do no harm.

A FACT that is not without its significance as affecting the future of Leadville is the growing quantity of sulphide ores which are now produced by some of the mines. It remains to be seen whether or not their appearance does not mean the depression of the average grade. It is certain that they will, to some extent, increase the cost of production, and another year may see every smelter in the camp provided with roasting stalls, which thus far the Harrison works have been the only ones to build.

A VERY interesting series of figures has been compiled by Mr. WILLIAM HOSEA BALLOU on the time of maturity of the funded debt of the railroads in this country, which is summarized in the following table :

1925	None mature.	1932	$37,652,380
1940	$90,000	1885	37,924,727
1977	508,000	1889	42,265,763
1942	917,000	1896	44,016,000
1970	1,000,000	1912	45,842,000
1933	1,350,000	1895	47,985,982
1984	1,824,000	1901	52,121,500
1980	3,000,000	1891	52,635,032
1976	3,182,000	1894	53,535,000
1924	3,880,000	1897	55,733,00
1914	6,525,000	1915	57,372,000
1928	8,000,000	1906	64,950,142
1923	8,188,000	1898	66,818,500
1929	12,111,300	1930	67,594,189
1884	13,785,809	1908	79,586,128
1886	14,844,600	1919	81,068,500
1926	16,503,000	1933	81,3?6,000
1916	19,305,895	1909	89,114,560
1887	19,602,068	1902	90,978,985
1951	22,550,000	1904	91,009,900
1889	24,675,000	1903	96,651,483
1917	26,520,000	1900	102,187,941
1913	27,200,000	1899	114,892,573
1888	32,138,100	1911	120,200,395
1927	33,397,828	1910	151,075,362
1909	33,547,400	1922	151,878,750
1892	33,928,520	1931	162,381,800
1918	36,245,588	1905	164,985,450
1893	36,300,597	1920	172,533,629
1907	37,061,448	1921	220,424,080

A fact which few apparently realize is, that as an investment the $3,184,415,200 of bonds have proved better than the $3,456,078,196 of railroad stock, the interest on the former exceeding the dividends on the latter by $47,263,946, and how large are the sums running at high interest is shown by the following table giving approximately the amounts paying the different rates of interest :

Per cent.	Amount.	Interest.
3 on	$4,000,000	$120,000
4 on	30,000,000	1,200,000
4½ on	35,000,000	1,575,000
5 on	620,000,000	31,000,000
6 on	1,397,000,000	63,820,000
7 on	991,000,000	69,370,000
8 on	100 000,000	8,000,000
10 on	3,000,000	300,000

The question is often asked whether there is no danger of a financial disaster in times when large amounts of bonds become due. Such a period would be from 1915 to 1922, when in the aggregate $750,000,000 are to be met. Mr. BALLOU holds that it will not, because the amount of money in circulation, at the present rate of increase, would be such that the railroads will find it possible to issue new series at possibly lower rates.

OUR IMPORTS OF IRON AND STEEL.

Though somewhat late, the Bureau of Statistics has issued a volume giving the imports and exports of merchandise classified by countries. The figures are worthy of a close study, because they reveal from whom, principally, we draw our supplies, and who our main customers are.

We have grouped the imports by the countries from which the supplies have come. Beginning with Great Britain, we have the following figures for the fiscal year ended June 30th, 1883 :

IMPORTS FROM GREAT BRITAIN.

	England. Net tons.	Scotland. Net tons.	Ireland. Net tons.
Pig-iron and castings	343,908	143,513	3,437
Bar-iron	34,325	674	.....
Band, hoop, and scroll iron	5,327	227	.....
Iron rails	5,790	.....	.....
Sheet-iron	10,560	126	.....
Scrap	31,952	2,391	150
Anchors, cables, and chains	817	.....	.....
Steel ingots, bars, and sheets	$4,679,008	$167,919	$105,875
Steel rails	108,302	.....	9,145

A second group is Belgium, Germany, France, and the Netherlands, and it should be noted that the bulk, if not probably all, of the iron and steel returned as coming from the latter country is really merchandise in transit from one or the other of the former two countries :

	Germany. Net tons.	Belgium. Net tons.	Netherlands. Net tons.	France. Net tons.
Pig-iron	9,507	10,894	5,475	3,645
Bar-iron	2,518	1,028	.....	.....
Steel ingots, bars, and sheets	$993,678	$3,947,004	$2,180,988	$35,741
Steel rails	3,285	4,410	.....	.....

In the aggregate, it will be seen these figures are large, and the fact that Belgium is so very large an exporter to this country of steel in its various forms is one which we believe very few are aware of. Together, continental works send us steel valued at upward of seven millions of dollars, exclusive of rails, while Great Britian exports to this country only about five millions of dollars in value. Other countries, of course, supply us with comparatively little iron and steel. It will suffice to state that Russia sends to our country nearly one thousand tons of sheet-iron, while Sweden and Norway ship 3869 tons of pig-iron, 19,727 tons of bar-iron, $69,998 worth of steel. It is interesting to note from how many quarters we get scrap-iron. Out of the aggregate of 70,964 tons, valued at $1,240,490, the following countries sent us in the fiscal year 1883 more

Digitized by Google

than 1000 tons each, thirty-one countries outside of those mentioned in the following table sending all the way from one to seven hundred tons:

IMPORTS OF SCRAP-IRON.

	Gross tons.
Argentine Rebuhlic	1,084
Belgium	1.452
Brazil	1,121
Denmark	1.770
Germany	12,611
England	31.952
Scotland	2,391
Canada	2,867
British East Indies	4,983
Netherlands	3,300
Peru	1,148
Cuba	2,149

Turning to the metals, exclusive of tin, the imports, of course, are small. Out of the 2751 tons of lead, England sent us 1034 tons, Germany 500 tons, and Mexico 596 tons. Copper ore came to us from Canada to the amount of 526,694 cwts., valued at $120,869. The bulk of the spelter and sheet-zinc, of course, comes from Germany, the record showing imports of 7820 tons of spelter and 667 tons of sheet-zinc, while 621 tons of spelter and 724 tons of sheet came from Belgium. A small quantity coming from England, and by way of the Netherlands, makes up the total of 8662 tons of spelter and 1645 tons of sheet-zinc.

From the detailed statement of the port of entry of the different classes of iron and steel, we select a few to show in which manner the business is distributed:

PORTS OF ENTRY.

	Pig-iron. Net tons.	Bar-iron. Net tons.	Old scrap. Gross tons.	Steel, ingots, etc. Value in 1000 dollars.
Baltimore	72,471	40	293	$1,153
Boston	40,984	31,970	1,708	2,947
New Orleans	6,962	278	24	21
New York	255,248	18,964	31.530	1,266
Philadelphia	79,270	1,618	12,784	76
San Francisco	20,217	5,044	14,800	47

It will be noticed that while Baltimore gets a fair share of pig-iron and a very heavy proportion of the steel, it gets little of any thing else. Boston imports nearly three millions worth of steel and a high proportion of the bar-iron, while Philadelphia, taking a good share of the raw material, is no very favorable place, apparently, to consign finished goods to. As for steel rails, it is principally the Southern and Pacific ports which are favored with that intruder, being, as we have had occasion to remark repeatedly, the weakest points. The following table will illustrate this fact:

IMPORTS OF STEEL RAILS, BY PORTS.

	Net tons.
Baltimore	1,292
Bath, Me	1,535
Beaufort, N. C	2,171
Boston	240
Galveston	5,603
Mobile	6,902
New Orleans	43,399
New York	3,333
San Diego, Cal	3,498
San Francisco	57,167

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

The Alice Mine of Montana.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Can you aid some of the Eastern stockholders of the Alice Mining Company to obtain late and reliable information about the condition and prospects of the property? What we desire is *dividends;* and if it is not possible to pay them honestly, we wish to know why it is not. When dividends ceased in 1881, it was understood that certain extensive and much needed improvements were to be made. The shaft was to be sunk deeper; the mills were to be reconstructed; the Magna Charta and the Valdemere claims were to be paid; and all this being done, we expected that the property would be in a condition to make larger profits than before.

It is generally understood that the improvements have been made, and that the company is out of debt. In September last, there were rumors that, with the greatly increased production and the accumulation of a reserve fund, dividends would soon be resumed. All the information gathered at the mine and mill by the enterprising local newspapers is favorable and encouraging. We hear that the shaft has been sunk to the 800-foot level, and that stoping has been begun there on the pay-chute. The vein is said to be strong and rich. On the 10th of November, or a short time previous to this date, the mine was reported to be producing 60 car-loads of ore daily, assaying from 150 to 200 ounces per ton; "better ore than any taken out for years." The Magna Charta was also sending from 50 to 60 tons of ore ot the mills daily. The value of the product for the month of October, according to the *Butte Miner*, was $105,836.63, and the disbursements $41,600. According to the *Salt Lake Tribune*, the shipments of bullion from the mine for the year up to November 5th amounted to 641 bars of silver, valued at $859,887.57. It is presumed that this information is correct. The product is large—at the rate of over a million a year—and the showing is favorable, but we have very little information about the management and the expenses. Is the property skillfully and economically managed? Are the ores properly worked? These may be questions for an expert to answer; but it is possible that some of your able correspondents at or near Butte may be disposed to throw some light on the subject.

STOCKHOLDERS.

PROGRESS IN THE MINING INDUSTRY OF YAVAPAI COUNTY, ARIZONA.

Special Correspondence of the Engineering and Mining Journal.

In looking over the work done this year in Yavapai County, we see that much progress has been made, although perhaps not as much as many persons expected, and might have expected at the beginning of the year. We have to record the suspension of work at the Tip Top mine, after a production of about $2,000,000. Whether it is a permanent stoppage or not time will tell. The mine reached a depth of over 800 feet, and throughout the ore has been high-grade; but the misfortune has been, that the vein was narrow and the wall-rocks very hard, making the mining very expensive. There are some "chloriders" at work in the neighborhood of the Tip Top who are doing well, the ores being sent to San Francisco or to Benson.

Some developments of copper ore have been made at Castle Creek, and a smelter erected; but, as is too often the case, the smelter was started before the mine was in a condition to supply the necessary ore, and a suspension was the natural result. In the Peck District, the year's results have been very cheering. The Tuscumbia mill, having passed into the hands of the Black Warrior Company, has been kept steadily at work for some months, thus enabling that company to develop its mine in a manner that it well deserves. All reports of the mine and its management are of the most satisfactory character. The latest reports from the Peck mine say that a splendid body of ore has been struck in sinking the mine deeper, quite worthy of the Peck in its palmiest days. The unwatering of this mine was started something over a year ago, and the ore taken from new openings has more than paid the expenses incurred in putting the works in order, after a suspension of several years. In the Turkey Creek District, several companies have been at work with varied success, but none very promising. Probably the less said about them the more satisfactory to those interested. The main feature of this district has been the discovery of the Pine Spring mine, probably the richest discovery of silver that has ever been made in the territories. The ore is horn-silver and the native metal. In sinking the first fifty feet, some $60,000 worth of ore was taken out—or rather, it netted that to the owners. Of course, this produced great excitement for a time, but not greater than was warranted by such a rich find. The ground was located for a long distance around the discovery, and some of the prospectors have found other bodies of ore, though not as rich as the first discovery. The Pine Spring shaft has reached a depth of 102 feet, and is still in ore. On the heels of this discovery comes another on Pine Flat, also in Turkey Creek District. This is also horn and native silver, and is said to surpass the Pine Spring discovery; but I have learned nothing of the facts as yet, and therefore can say nothing more of it. The rocks of this district are mainly syenitic gneiss. The ores are in most all cases high-grade, but the deposits, so far as known, are not continuous. Still, in no case have they been tested to any depth greater than 100 feet, and seldom that, and but little drifting has been done, so that a positive opinion can not safely be given.

In the Hassayampa District, the Dosoris and Blue Dick mines have been holding their continuous and profitable course, particularly the former mine. I should like much to be able to give you statistics of these and other mines, but that is not possible, as most of the companies of this section are, more or less, private corporations, and therefore reliable figures are not to be obtained, and it is better not to give any rather than to guess at them. There are some chloriders at work in this district, whose ores are hauled to Ash Fork, and find their way to Denver and elsewhere.

In the Lynx Creek District, the Howell Smelting Company has been in continuous operation during the year, and has sent large amounts of bullion out of the country. Nearly all the ore smelted has come from the Belle mine. In the summer, a mill of ten stamps was added to the works, which have been kept running on ore also from the Belle. No other work, except that of prospecting, has been done in this district, and that mostly on old claims. No discoveries of moment have been made.

The next point of interest is the Aqua Frio District, in which is located the Copper Mountain Mining Company's works and the Silver Belt mine. The Copper Mountain Company erected a water-jacket smelter of 30 tons capacity in the spring, and put it in successful blast, but, finding that the mine was not sufficiently opened to keep it going, stopped after a ten days' run, and since then has been engaged in opening the mine. The results of the run made were satisfactory, and it was simply a question of a supply of ore. Good progress has been made in opening the mine, and it is expected that the company will soon be able to make a fair start with the smelter again. At the Silver Belt, a hoisting-engine has been erected, the shaft sunk 130 feet deeper, the drifts are opening fine ore, and all indications are, that the mine is proving richer in depth. There has been a steady production of ore the whole year, part of which was smelted at the Howell works: but most of it has been hauled to Maricopa, for Benson, or to Ash Fork, for Eastern smelters. They have been engaged the last few months, very successfully, in concentrating the lower-grade ore, large quantities of which are on hand in the dump, which is the accumulations of several years.

The porphyritic slate belt in which the Copper Mountain mine is situated crosses the Aqua Frio near that mine, and continues northward to the Black Hills, skirting those hills on the western slope or foot. It has been prospected to a limited extent throughout its length, and several fine openings or discoveries of copper and silver ore have been made; rather I should say argentiferous copper ore, as it is mostly gray sulphuret with heavy oxide and carbonate croppings. The most notable of these discoveries are the Homestake and Rambo mines, at the southwestern foot of the Black Hills. At the former of these two mines, much fine high-grade silver ore was encountered at the start, and extending for a depth of from 20 to 30 feet. The shaft has been sunk to a depth of a little over 100 feet, and the show for a large copper mine is of the most satisfactory nature. At the Rambo mine, two shafts have been sunk, respectively 20 and 55 feet deep. Both of these shafts started on a small streak of ore; but they widen out so much that the bottoms of the shafts are solid ore from side to side. The ore is a mixture of carbonates, and oxide with some gray sulphurets, and will average over 30 per cent in copper, and carries from $30 to $40 in silver per ton. Here and there,

Digitized by Google

silver ores occur, and assays as high as $1400 in silver have been obtained. Several other claims in the immediate neighborhood have been opened to some extent, and are showing well. I am strongly of opinion that it is destined to be a very prominent camp in the near future.

The event of the year for this county has been the opening of the mines of the United Verde Copper Company, situated on the northeastern slope of the Black Hills. This work started with the bonding of the Wade Hampton claim last year; and after some work in further proving the claim, it purchased it and several others adjoining, so that the company has now some twelve or fourteen claims. The developments showed large bodies of copper ores, and in the summer a 40-ton smelter was erected. Before this, however, could be done, a road at the expense of some $30,000 had to be built across the hills. The smelter was got into blast, and has been in continuous operation for some three months. The first run of 30 tons of bullion showed a yield of between 17 and 18 per cent of copper. Since then, the ore has been of a higher grade, and the further development of the mines has shown large amounts of silver in the form of chloride and native. The occurrence of the silver has proved most remarkable both in quantity and mode of occurrence. The ore affords in abundance magnificent specimens of plate silver in the fractures of the solid oxide ore, and frequent chunks of horn-silver are mixed with the copper ores. The result in the furnace has been, that the bullion has run up to as high as $900 in silver to the ton, and from present appearances, it is not possible to say what figures may be reached. The profits, so far, have been such as to pay for all the outlay made, and afford a dividend besides, which was paid last month to the owners. This has been done with one smelter, and the show of ore is such that it would be as easy to keep six smelters going as one, as the one has been supplied with ore from the shafts and drifts only. We feel safe in saying that the property can not be equaled by any other in the States for richness and quantity of ore. I hope before long to give you a more detailed description of the mine, and some figures showing what has been accomplished. Work has gone on quietly and patiently, so that probably but little has been known outside of the county and by those interested; but I shall be much surprised if the wonderful developments do not soon set the mining interest of this county in a blaze.

It seems, from the past history of this section, as if some such surprise was needed to give us the start that we want, and that such a rich mineral country deserves. That the ores are here is plain to all who have spent the time to examine. This is more particularly true of the copper ores which are found in such abundance, and in so many different districts, nearly all of which are rich in silver and some gold. I think the time will come when copper from this region will be looked upon as lead is at Eureka and Leadville, that is sold for what it will bring, the silver and gold being the main products of the mines. I will not now attempt to outline the run of the main belts of copper-bearing rocks as far as known, which are very extensive, and every few days we hear of new discoveries.

Much is said of the carbonate camp on the Cataract Creek, near the Grand Cañon, in the north end of this county; but not being able as yet to get any thoroughly reliable data on the subject, I shall leave it for another time. Some say it is to surpass Leadville in extent. The belts or bands of ore show themselves in the cliffs of the cañon of Cataract Creek, and the difficulty of access to them so far has much retarded the proper investigation. Yours, YAVAPAI.

AMERICAN SOCIETY OF CIVIL ENGINEERS.

The society met at eight P.M., November 21st, Director George S. Greene, Jr., in the chair; John Bogart, Secretary.

A paper by S. H. Keating, Member Am. Soc. C.E., upon the Shubenacadie Canal was read. This canal is located between the city of Halifax, Nova Scotia, and the Basin of Mines, an arm of the Bay of Fundy. It was begun in 1826, and the intention was, to build it so as to accommodate vessels drawing eight feet of water, with the idea that, at comparatively small additional expense, it could be used by vessels drawing eleven feet. It was to have 15 locks, 87 feet in length and 22½ feet in width, with a lockage ascending from Halifax of 95 feet 10 inches, and, descending to the Bay of Fundy, of 95 feet 4 inches. The total length is about 54 miles, the greater portion of which was to be in the Shubenacadie River, and in a chain of lakes existing along the line of the canal.

Mr. Thomas Telford, the celebrated engineer, made a very favorable report upon the proposed canal and its prospects. Up to the close of 1831, £72,000 had been expended upon the work, which was, however, in an entirely uncompleted state. Some of the locks near Halifax had not been begun, and large and expensive work remained to be done upon the line of the canal. All the available capital being exhausted, the works were abandoned, and fell into ruin, never having been completed on the original plan. In 1856, a report was made by Mr. W. H. Talcott, C.E., upon a scheme for completing the works upon a very much smaller scale than at first proposed, substituting for certain of the locks an inclined plane near Halifax, with a lift of 55 feet, and a similar plane, with a lift of 33 feet, at another point; the planes to be worked by hydraulic machinery. This report was adopted and the work was completed in 1862, at a cost of $200,000. The diminished canal has, however, proved a failure as a commercial enterprise, and since 1870 no trade of any account has been carried on through it.

There was also presented a description by Charles C. Smith, Mem. Am. Soc. C.E., of an hydraulic canal built at Minneapolis, Minn., during the severely cold winter of 1881. This canal is under Main street, Minneapolis, its entrance being at right angles to the street. It is covered with a semicircular rubble-stone arch of 17½ feet span, and where the line turns the angle of 90 degrees the abutments of the arch were built of curved lines of the radius of 31½ and 48¾ feet. The arch was built of rubble masonry, of stone varying from 4 to 6 inches thick, and from 18 to 36 inches long; the joints at the soffit being slightly hammered off to approximately form beds conforming to the radial lines of the arch. The mortar was made of one part Louisville cement to two parts of sand, and was mixed in hot water without salt. During its construction, the weather was extremely cold, the frost having penetrated the ground to the depth of six feet. An examination of this work having been made quite recently, it was found to be perfectly sound and free from any indication of settlement or rupture two years after its construction.

A discussion followed by the members present, more particularly in reference to the best methods of laying masonry in very cold weather, the experience of a number of members being favorable to the use of a strong solution of salt in the water with which the mortar was made.

The recent adoption of a system of time standards by the railroads was discussed, and Prof. Julius E. Hilgard, Mem. Am. Soc. C.E., gave a statement as to the measures which were in progress in reference to securing a standard prime meridian, together with other measures pertaining to the determination of standard time by the various nations of the world. He also described the results of the recent meeting at Rome, Italy, of the superintendents of the geodetic surveys of various nations.

BESSEMERIZING COPPER MATTES.

During the last days of his life, Mr. Louis Gruner was preparing for publication a short paper on the Bessemerizing of copper mattes, to which frequent reference has been made in the columns of the ENGINEERING AND MINING JOURNAL. This paper has now been published in the *Annales des Mines*, and from it we gather the following data on Mr. Pierre Manhès's method:

Beginning in 1880 at his copper-works at Védènes, M. Manhès started working with matte containing from twenty-five to thirty per cent of copper previously melted in a crucible. As was expected, the sulphur and iron were oxidized very rapidly, the former escaping in the form of sulphurous acid and the oxide of iron forming a liquid cinder with the silica of the lining of the converter. During the first few moments, every thing went well. The heat developed by the combustion of the iron and the sulphur sufficed to keep the metallic bath in a liquid state, but the difficulties appeared toward the end of the operation, which changed very suddenly. The regular oxidation produced by blowing in air was succeeded by a violent ebullition, accompanied with ejection of cinder, and after a while grew so strong that the bath, matte, and cinder were thrown out of the apparatus. On the other hand, as the sulphur was oxidizing, the metallic copper, having a greater density than the matte, sank to the bottom of the converter and chilled there. The tuyeres were gradually obstructed by metallic copper, so that it became necessary to cast the metal before the upper part of the bath had been thoroughly desulphurized. Therefore there was generally a residuum of matte lighter and more fusible than the pure copper. The trials with mattes varying in their percentage of iron and copper were multiplied and changed in many ways, but so long as the ordinary Bessemer converter, with its vertical tuyeres, was used, the difficulties were always the same. It was always necessary to stop the operation before the iron and the sulphur had been entirely eliminated. This, undoubtedly, was what also happened during the earlier experiments in England, and this probably explains the failure of those trials. M. Manhès having recognized that the principal difficulty was the outgrowth of the cooling action of the blast on the copper, substituted horizontal for the vertical tuyeres, forcing the blast into the bath at a point above the bottom of the converter. The blast-box at the base of the converter was replaced by an annular blast-pipe provided with a series of lateral orifices through which the blast was horizontally forced into the metallic bath. With the plant thus modified, the copper did not chill. As fast as it was produced, it sank below the level of the blast, and was kept in a liquid state until the end of the operation. Thus, all the matte could be desulphurized and a copper produced which retained no more than one and a half per cent of foreign substances as a maximum. To overcome the difficulties due to the presence of large quantities of cinder, a number of different processes were adopted according to the character of the mattes. With rich mattes carrying from 50 to 60 per cent of copper, these cinders give very little trouble. By adding quartz, the corrosion of the walls of the converter is diminished; and by introducing into it a certain quantity of manganiferous pig-iron, greater fluidity is given to the cinder. In the case of poor matte, the quantity of cinder becomes so large that, in order to carry out the operation successfully, it is necessary to get rid of it and in some cases even repeat the operation a number of times. These preliminary trials, carried out for a year at the Vedénès works, proved that it was not alone possible, but that it was easy to rapidly convert copper matte into blister copper containing only one to one and a half per cent of foreign substances. The process has been carried out on a working scale in the Old Royal foundry at Eguilles, near Sorgues, where a large water-power is available. Three stacks have been put there for smelting ores, two cupolas for melting matte, and three converters for Bessemerizing the matte. This establishment began operations toward the close of 1881. At an early day, a second works, having also three converters and the necessary smelting-furnaces, will be completed. Now, with three converters, working alternately, the weekly production varies between 85 and 100 tons of copper. The working has been retarded by the great difficulty of procuring copper ores. In France, there are very few mines producing this metal, and the difficulty of marketing small lots of ore has, until now, prevented the opening of known deposits. As for foreign ores, Italian, Spanish, etc., they have been bought for many years by English works, and it is difficult to get the miners to deal with new purchasers; still there is a tendency to shipping at Marseilles, and all the ore which can now be procured is treated. The copper produced is refined at the works in an ordinary furnace, and the entire product is rolled at the Védènes works without the slightest difficulty. The ores are very variable in character. Among them are cupriferous pyrites from Saint Georges d'Hurtières, in Savoy, which are pure but poor, rich but impure ores from Aveyonan or the Pyrenees, ores from Toscana containing from seven to fifteen per cent of copper and from thirty to forty per cent of iron, and ore coming from Tadergount in Algeria, carrying as much as from ten to fifteen per cent of antimony. These ores have been employed mixed with the roasted ores from the manufacture of sulphuric acid, with scrap and cement copper. According to their character, they are smelted in furnaces about sixteen feet high or in stacks only seven feet high above the tuyeres. The great variety of the ores is one of the drawbacks of the market now, because from day to day it leads to the production of mattes carrying only from twenty to twenty-five per cent of copper or a raw material contain-

Digitized by Google

ing as much as fifty per cent. This naturally makes the Bessemerizing a difficult matter, since there are variations almost every day in the composition of the matte treated. The manufacture would be very much more simple if the works could procure mattes of a uniform character. The converters which are used at Eguilles are 4·06 feet in diameter and 6·06 feet high. About one foot above the bottom is the blast-pipe provided with eighteen 0·3-inch holes. The operation does not differ very much from that in the Bessemer steel converter. The vessel, heated to redness, receives a charge of one ton of melted matte and is blown at a pressure of one inch of mercury. The temperature rises rapidly, while thick sulphurous gas escapes, and it is only after fifteen or twenty minutes that the vapors become clear. When the matte treated is poor, casting must at once be proceeded with, because otherwise a very violent reaction takes place. With rich mattes, the operation goes on without any difficulty, and a copper containing from ninety-eight to ninety-nine per cent and cinder carrying from three to five per cent of copper are produced. The latter is put through with the smelting charges. In the beginning, it was not possible to make more than from ten to twelve operations in one converter, and the lining was often completely corroded even after seven or eight blows. Now, with the same matte, from fifteen to sixteen and even eighteen operations are made on one lining. At the Eguilles works, mattes containing more or less arsenic, antimony, lead, zinc, and tin have been treated, and these substances are either scorified or volatilized. It would seem that arsenic and antimony ought to remain with the copper; but a number of operations have been made with very impure mattes, and the ease with which the copper produced from them has been rolled furnishes the proof that the arsenic and antimony had almost entirely disappeared. It seems probable that the oxides of these two substances are mechanically carried off by the blast, so that the reducing action of the copper can not take place. Cobalt is partly scorified and partly remains with the copper, while nickel and bismuth are both concentrated in the product. The Bessemer process does not, therefore, remove these substances, with which none of the methods actually in use is able to deal. The elimination of the arsenic and the antimony was one of the most important points to settle, and many trials have shown that, for the greater part, they disappear, and that a metal is produced which will stand ordinary tests. The copper obtained in the converter has a very constant composition, varying little from the following: Copper, from 98·05 to 98·08; sulphur, from ·09 to ·08; and iron, from ·06 to ·04. At the Eguilles works, the machinery is run by water-power. If steam had to be used for the different blowing-engines, a consumption of from three to four tons of coal per twenty-four hours would be required for an output of from three to four tons of copper. For the fusion of the ores in blast-furnaces, between 280 and 300 pounds of coke per ton of ore carrying ten per cent of copper are required for melting the mattes, heating converters, etc.; there is a further consumption of coke of from fifty to sixty pounds per hundred pounds of copper. Taking into account waste and loss, the consumption may rise to two or two and a quarter tons of coke, equivalent to three or three and a half tons of coal; and for refining, about 1400 pounds of coal per ton of copper may be counted upon. The total consumption of coal, therefore, would be about five tons per ton of marketable metal, against from thirteen to sixteen tons by old methods. For works producing one hundred tons of copper per month, the number of men does not exceed seventy, which corresponds to about twenty days' work per ton of copper. In a larger establishment, better fitted out with machinery, this figure would be notably reduced, because at the Eguilles works the hoisting of the ore and mattes, the movement of the converters, the crushing, etc., is all done by hand. At these works, the cost of treatment per ton of refined copper is not more than from 160 to 170 francs, in spite of the fact that the general expenses are large and coke costs 35 francs. In England, with fuel less than half that price, the cost of treatment is estimated to be between 320 and 350 francs per ton of copper by the old method. It is evident, therefore, that, under the same conditions the cost of treatment by the Bessemer process would not be more than one third of the old method. M. Gruner did not hold that the Bessemer process would modify the metallurgy of copper in as radical a way as it did that of iron and steel. In any case, there is a great future for the new method. The labor and the consumption of fuel are reduced very largely, and in those countries where coal is dear the process will permit of utilizing ores which have not, until now, been available.

FREIGHT RATES ON BASE BULLION.

The Leadville *Herald* thus touches upon a topic already discussed by us: The depressed condition of the lead market, and the consequent close margins on which the mines and smelters of Colorado are working, have resulted in renewed exertions toward securing railroad freight concessions that have heretofore been denied Colorado. There is no question but that, on heavy lead ores. Leadville smelters are now running at a loss, and that the present situation can not last any length of time without disastrous results. The smelters all realized this fact, and have recently begun working in unison, toward securing a partial relief from the burden imposed upon the smelting industry by reason of the excessive freight tariff on base bullion. In this measure, we understand, they have the hearty co-operation of local agents, division superintendents, and other subordinate officers of the Colorado railroad companies. In fact, there are few railroad men who will not candidly acknowledge that freight rates on bullion from Colorado points to the Mississippi Valley are excessive. Also, that an increased business would follow a reasonable reduction on this class of freight, and that in the end the railroads would be large gainers by a more liberal dealing with the mining and smelting interests of the Rocky Mountains. The effort is making in a quiet but determined manner, and nothing is left undone that might assist in convincing the railroad officials that a reduction of rates is absolutely necessary to the continued prosperity of Colorado's mining interests, and that a reduction would consequently redound to the benefit of both parties. A great many mines have already reduced their production, and many of those now shipping are only enabled to continue at the expense of the smelters, with whom they have contracts that are simply ruinous to the latter, under the existing state of affairs. There was a time in the history of this camp, when the base bullion produced contained from four hundred to eight hundred ounces in silver to the ton, and could easily bear the great expense of transportation. At present, however, the bullion does not average one hundred ounces, and the value of Colorado's base bullion product is nearly as great in lead as in silver. Under such circumstances, it is apparent that Leadville lead ores are no longer mined principally for the silver, but that the lead must also yield some return; otherwise, the ore will not be extracted and smelted. The costs of mining, smelting, etc., have reached the lowest possible figures, and the only factor in the great industry that has not yet contributed its proportion toward reducing the cost of Colorado lead to a minimum is the railroad. So far, negotiations have advanced very favorably, and, judging from expressions by persons familiar with the matter, there is little doubt but that reasonable concessions will be made.

THE PUMPING-ENGINE OF THE BINDWEIDE MINE, GERMANY.

(WITH SUPPLEMENT.)

The shaft of the Bindweide mine has a depth to the level of the upper adit of 50 meters, and to the level of the deep adit of 86 meters. Below the latter, it is 57 meters deep, a level having been started at 50 meters' depth, which is also to be the distance of future deeper levels. The water is to be delivered to the deep adit, to which also the ore is to be hoisted. Through the upper part of the shaft, the coal for the boilers is to be hoisted from the tunnel level, and is to serve also as the outlet for any rock that it may be impossible to dump into the old workings. For this reason, the dimensions of the shaft in its upper portion are less, being only 4·355 by 2·02 meters, while the lower part is 4·355 by 2·975 meters, divided into two hoisting compartments 1·08 by 1·6 meters, one pump compartment 2·555 by 1·44 meters, inside dimensions, and ladder compartment 0·8 by 3·555 meters.

Careful measurements, carried on for more than two years, showed that the average flow of water from the upper tunnel was 0·403 cubic meter, the maximum being 1·003 and the minimum 0·129 cubic meter. The lower tunnel discharged water at the average rate of 0·960 cubic meter, the maximum being 2·820 and the minimum 0·700 cubic meter. The water flowing from the upper tunnel will certainly not in the future sink to where the pumps must hoist it, and it is to be utilized as feed-water. It was assumed, however, that the water on the lower tunnel would drop lower. It was estimated that the pump on the first deep level would have to cope with a quantity of water equal to the maximum of the lower tunnel, that is, 2·82 cubic meters per minute. For the second level, 2·50 cubic meters was assumed as the maximum; and for the third and fourth, 2·25 cubic meters per minute each. Assuming an average piston speed of 0·75 meter per minute, the dimensions of the plungers of the pumps were computed to be: Diameter of plunger of pump, 1st deep level, 0·42 meter; 2d deep level, 0·40 meter; 3d and 4th levels, 0·37 meter.

In view of the wide variation in the flow of water, it was necessary to choose an engine capable of adapting itself to a wide range of duty. The Kley system was therefore chosen, with one cylinder and without condensation. The dimensions had to be such that cutting off at one quarter stroke and with a pressure of steam of six atmospheres above atmospheric pressure, the engine would be capable of pumping the maximum quantity of water noted from the different levels, down to the 200-meter level. The calculation was made with the following formula:

$$\frac{\pi D^2}{4} p' \left(1 + \frac{0{\cdot}332}{p'} - \frac{p}{p'} - \frac{r}{p'}\right) K \times 2L = WL$$

in which D is the diameter of the steam-cylinder, p' the absolute pressure of the steam after expansion, p the absolute pressure of the steam before expansion, r the average absolute pressure in front of the piston, K the useful effect of engine and pumps, L the stroke of piston and pumps, and W the total weight of the columns of water to be moved. Now p is equal to 6 atmospheres or 70,000 kilograms, p' one quarter of p, or 17,500 cutting off at one quarter stroke, r assuming much compression is 1·5 atmospheres, or 15,000 kilograms, and the useful effect K is 0·70. W is found as follows:

	Kilograms.
Weight of column of 1st level pump ..... = 0·1385 × 50,000 =	6,925
" " 2d " " ..... = 0·1257 × 50,000 =	6,285
" " 3d " " ..... = 0·1075 × 50,000 =	5,375
" " 4th " " ..... = 0·1075 × 50,000 =	5,375
Total ..... W =	23,960

Using these values, D, the diameter of the steam-cylinder, is found to be 0·90 meter, and L, the stroke, twice the diameter, or 1·80 meters. As the piston speed chosen was 0·75 meter, the number of revolutions of the engine is 12·5, making horse-power 120.

We have already dwelt upon the characteristics of the Kley system in a former issue of the ENGINEERING AND MINING JOURNAL, and our Supplement will fully suffice to show the design of the Bindweide engine. The gear is so arranged that the engine stops when the piston reaches the lower position, and does not begin a new stroke until started by the cataract.

PUMPING WATER THIRTY-SEVEN FEET BY SUCTION.—David P. Stewart, of Buffalo, N. Y., writing to the *American Machinist*, says: In all theory, and in my practice, I have been led to believe that it was impossible to raise water by suction over 28 or 30 feet, and that it was not good practice to pump it over 25 feet. But my attention was called to the fact, that at a certain establishment in this city they were pumping water by suction 37 feet, and, having considerable curiosity, I called to investigate. The engineer stated as a fact that they were pumping water by suction 37 feet, that is, from the surface of the water to the suction-valve of the pump, 37 feet, with but slight variations. About 25 feet from the bottom end of the suction-pipe is a tee with nipple and elbow. From this elbow, a stand-pipe of the same diameter of the suction-pipe extends to the same hight, and is covered with a cap. There is a check-valve at the bottom end of the suction-pipe. The explanation is: Fill both pipes with water, then screw the cap air-tight on the top of what I should call the stand-pipe, the action of the pump will suck the water out of the stand-pipe and form a vacuum in it that will sustain the water in the suction-pipe, so that the pump will lift the water the 37 feet without any trouble.

THE SEVEN NATURAL WONDERS OF THE BAKU PENINSULA, AS SEEN TWO HUNDRED YEARS AGO.*

By Engelbert Kaempfer.

[Engelbert Kaempfer, the son of a Lutheran minister of some property, was born in 1651 at the village of Lemgo, the capital of Lippe, Germany. His first long journey was to Holland, in his seventeenth year. After that, he studied successively two years at Lüneburg, two at Lübeck, two at Dantzic and Thorn, two at Cracow, five at Königsberg, and over one at Upsal, until his thirty-second year. Then, in 1683, as secretary to a Swedish embassy, he traveled through Russia to Persia. On the way, they were detained a month at Shamachia, and he made thence his excursion to the Baku Peninsula. When, at the end of two years, they had gained their object, a commercial treaty, at Ispahan, he for the sake of further travel joined the service of the Dutch East India Company as surgeon, went to Bunderabbas on the Persian Gulf, and spent about a year there. Within the next two years, he went to Tiflis, and was phy-ician to the Georgian prince; but then became ship's surgeon on the Dutch fleet in the Persian Gulf, and visited the coasts of Arabia, India, Ceylon, Sumatra, and Batavia in Java. After eight months here, he sailed in 1690 by way of Siam to Japan for a stay of two years; and at length returned by Batavia, the Cape of Good Hope, and Holland to his native town, where he arrived in his forty-fourth year, and was henceforth court physician until his death at sixty-five, in 1716.

Of his voluminous and handsomely illustrated manuscripts and notes, none underwent the cost of engraving and printing in his lifetime except the *Amœnitates Exoticæ*, a volume of over 1000 small quarto pages of essays intended as a sample of what he had to offer the public. Some manuscripts had been lost at sea; the rest, after his death, were purchased by Sir Hans Sloane, the celebrated physician and naturalist, whose magnificent collection of books, manuscripts, and natural history specimens became in 1753 the nucleus of the British Museum. He encouraged the English translation and publication of Kaempfer's papers, beginning with the history of Japan, that came out in 1727. The other thirty-six manuscripts, large and small, have never been published, and are doubtless still in the British Museum, as they were a hundred years ago. Two other manuscript copies of the history of Japan were discovered at Lemgo, and from them a German edition was published in 1777, with a short life of Kaempfer.

His published works have placed him in the very foremost rank of travelers; and that is the less surprising since he was already one of the most learned scholars of his time before his Eastern travels began. He is very clear, precise, and conscientiously truthful in writing, very painstaking in observing, and very intelligent and sensible in seeking the causes of things, not credulously swallowing marvelous tales with eagerness, nor ever looking for the miraculous rather than the natural. Few, as Hildreth says, have equaled him in picturesque power; and his descriptions, though so complete and finished, are yet unaffected and natural, with much quiet humor.]

NATURAL GAS.

Thence we came from the south to the "Burning Field," white with sand and sprinkled with ashy dust. It gave out sulphury jets from numerous crevices, a varied and pleasing spectacle. For some crevices blazed with a great tumult, and struck horror into the spectators, with fire scattered violently about; others emitted gentler flames, and allowed any body sufficiently close access; others exhaled fumes or scarcely visible vapors that smelt of the very disagreeable spirit of naphtha. The phenomenon occurs throughout a space eighty-eight steps in length and twenty-six in breadth. The fissures were wonderfully narrow, gaping not more than a foot or a palm; some shorter and drawn into a semicircle, others crooked with a long curved bend; just as I have shown accurately and to the life in the subjoined picture, to shorten the description. The edges of the chasms and the ground itself, when the superficial dust is removed, displayed a rotten, light stone almost like pumice; the material of which seemed to consist of bivalve shells and very minute spiral ones. We found about ten men staying there, occupied in different work about the fire; for some with brazen and earthen pots set over a crevice that was not too violent were preparing breakfast for the inhabitants of the neighboring village, Sroganni Ateşgâwa, so called from this fire; others with stones brought from somewhere else and piled up in a heap were burning lime, and were arranging it, when made, in heaps to be carried away in boats; and a couple of foreigners, Indian fire-worshipers descended from the race of the ancient Persians, were sitting quietly near an inclosure built by them, making offerings to the eternal God, while gazing at and worshiping the flame that burst forth. One of the lime-burners came to us, and offered to show something more unusual, if we would be pleased to give him money for the service; and when we had paid it, he fixed upon a fire-shovel some flocks of cotton torn from his tunic, and set them afire; the flame so caught he very quickly transferred to a more distant crevice free from fire and flame. By that very act, the vapor, not at all visible before, broke out into a very high flame, a pleasing and unexpected appearance, but one that in a short time vanished again. Among the prodigies of nature, the first rank belongs to this phenomenon, seen from time immemorial in this part of the peninsula, but not in the same place; for half a mile before you arrive there, seven crevices are seen in one line, from which, formerly, the same flame blazed, and, after it had been extinguished, it burst out in the next place that I have described. Like jets of fire occur here and there in the defile of the Caucasus; of which they call the nearest and most conspicuous those of Mount Shubanai, distant four stages hence.

LIGHT OIL.

Returning thence two miles northwesterly, there was another remarkable thing, and that was a spring of white naphtha, in so very obscure a place that any one coming there would have taken no notice of the liquid if he had not been told. The place has the appearance of an irregular lake or fish-pond, about fifty steps in breadth and a hundred in length, with the shore depressed a couple of fathoms below the general surface of the ground. The bottom is muddy and slippery with clay, for only in the middle was there salt water standing a palm in depth. In its western end there were two wells several steps apart, narrow and, as they said, forty fathoms deep; in which naphtha that had seeped in from subterranean veins sparingly and as it were drop by drop was standing in moderate quantity, to be taken out when wanted. The well-mouths were not surrounded by any railing or wall or closed by covers; only stones placed around strengthened or indicated the mouth, and some bushes planted there protected the well from having small animals fall in. Not far off, there was a third well, but it had long ceased to drip, and exhaled no longer any odor to the nostrils. In the middle of the pond, stones lying in circles and sunk in the water showed the place of seven wells from which liquid had formerly been extracted; for when the passages have become obstructed from some cause, a neighboring place has to be dug until channels are found that flow. Here I was especially surprised at two things: (1) that the extremely volatile liquid is preserved in this open cavity without loss of substance, strength, and crystalline clearness, whereas it can not do so when shut up very closely in earthenware vessels; (2) that such a very rare deposit of nature may be left without any inclosure or custody. In our country, no one would dare to leave it so; if we did not wish to invite thieves to draw it off and curiously mischievous rascals to sacrifice the fountains to Vulcan by setting fire to them. For this naphtha exhales a most volatile gas, by the help of which it catches in an instant the flame of a burning hearth or lamp, and, once kindled, blazes inextinguishably; as the same thing is lengthily related about the naphtha around Ecbatana, by Plutarch, in his life of Alexander, § 12. But the fire catches in fresh liquid, not in that which has been long gathered and kept uncovered, and less in that which has changed from the clearness of water to an amber yellow. For this liquid is oily, extremely thin, like rectified spirits, pellucid, exceedingly penetrating, and easily taking fire. The name is no new discovery, but has been celebrated for many ages, in Strabo, l. xvi., Plin. l. ii. c. 105, Plutarch's life of Alexander, who say it flowed near Babylon, Susa, Arbela, and Ecbatana, cities called to-day Bagdad, Shushter, Ardebil, and Tabriis. It is called, however, by the Turkish name *nafth sefiid*, that is, white naphtha, not from its having such a color, but to distinguish it from the more imperfect kind, that is in fact black, thick, and opaque, to fountains of which we shall come afterward. Although the present naphtha has many and remarkable properties in medicine which Dioscorides, l. i. c. 101, relates, I have never known among the Persians any use for it except to dilute their varnish; for the admixture has given it superiority, and gives incomparable luster to the vessels it is spread upon; indeed, to varnished things that have become dull with use it immediately restores the luster. The masters of the art in Southern Persia prefer the naphtha of Susa, which they distinguish from that of Shirwan only by the characteristic that, when stirred up with varnish according to the rules of the art, it foams promptly, while this does so in a less degree. If you would like to know the nature of Persian varnish, take the following description: Gum sanderuus, when it has been dissolved artificially, is boiled down with linseed-oil to the thickness of an unguent, and so prepared is kept for future use under the name of *rochanni kamuun*, that is, varnish-butter. Sanderuus means sanderach, but consists of large and shapeless lumps, which are brought hither from inland India by Gujarat; you would say that it was amber, except that it is more fragile. When they wish to brush on this varnish, they stir it up with a small rod along with a sufficient quantity of naphtha; and when it is properly diluted, they spread it very thinly indeed with a very soft brush upon any wooden or paper work that has previously been painted in various colors according to taste, and on the top floor of the houses (which in this climate are without roofs) or in places remote from dust they expose it to the rays of the sun, by the heat of which the volatile naphtha with the linseed-oil disappears in a few hours, leaving a most brilliant hard surface; in the same way as in separating gold from silver, when the quicksilver has been removed by fire, the luster of gold remains.

HEAVY OIL.

Going thence two leagues to the west, we reached, in the middle of the peninsula, a third extremely remarkable place that produces black naphtha. This is called *kara nafth* or black naphtha (in Turkish, now the popular language there), both to distinguish it from the more limpid naphtha already described, and because it is foul, dark, and black in color; in fact, very earthy and of inferior quality. The field where it occurs extends from west to east some hundred steps; and the whole space is black with the oil spread on it as if covered with pitch; for when it has dried, it hardens into such a substance. The very vapor gives out a heavy odor, displeasing and almost intolerable to the nostrils of the more delicate, even though they go away to quite a distance. The liquid does not gush out above the surface of the soil, but flows along through the hidden parts of the earth in deep channels, impelled forward, as they say, from the bowels of the overhanging Caucasus, until it falls into the sea close by or gives nourishment to the flames in the "burning field," if it be not intercepted in this place. Wells for that purpose have been dug here at various points and without order, very numerous, rude, narrow, sunken vertically. Some of them yield perennially an abundance of flowing oil; others with intermitted veins have no longer any liquid; others, not having found the channels, have been made in vain. They have a depth of thirty ells and more (in round numbers they say forty); not because the veins flow at that depth, but because they need a deeper cavity in which the liquid that drips out at night can be held until, with returning day, it may be extracted by the workmen. There is no need of much skill in digging; for the soil is clayey and compact, so that it can, without danger to the digger, be dug to any desired depth without any frame-work to keep the sides from caving in. The extraction is done by manual labor with skin bags let down either by hand alone or with a little pulley. One well was richer than the other, surrounded by a curb or stone wall and closed in by a pretty large house built over it, and deeper than the rest and much larger; and in it the naphtha flowed like a torrent with a remarkable noise. The product was extracted with the help of a machine built above, which two horses, by turns moving in a circle, kept revolving; for, except a few hours at night, it did not cease to work. They attributed the richness of the well to the sanctity of the place, in which they say a pious man formerly lived, one of the sacred race of the imams. Another house near that one had a

Digitized by Google

vaulted chamber, seven steps in breadth, seventeen in length, and of a depth not measured by me, into which, as into safe keeping, a certain quantity of liquid was poured, especially that of the neighboring fountain and hence was called the naphtha store-house; for it was extremely suitable not only for preserving it, but for displaying it, as it was open at each end and built with steps by which you could descend according to the degree of fullness. The oil (inclosed in sheepskins) was carried away in four-wheeled carts to the cities Shamachia and Baku; and from the former place on the backs of camels to all Media, and from the latter was to be carried by sea to Hyrcania, Usbecia, Circassia, and Daghistan. Its only use is to serve for the oil of lamps and torches, which on being kindled give out light with a larger flame than is desired. The opposite shore, Nagajum, does not need this oil; for it has plenty of sturgeon's oil with which both food is prepared and fuel is furnished for lights. About the yield and price of the naphtha I learned this: Thirty-two workmen labor daily, all inhabitants of the adjacent village, to each of whom are paid in general seven *abassi* a month, to others eight, that is, about two rix dollars. Daily 80 four-wheeled carts are sent hence, each loaded with seven or eight skin bags according to size; of which the smallest hold ten, the largest twenty or more *man* or *batman* of the measure of Tabriz, which is equal to nine Belgian pounds. Calculation then shows that about eight to ten thousand *batmans* [say 300 barrels] are extracted and carried away every day, for which, nevertheless, the workmen liberally substituted 100,000; whence the annual return in royal money, subtracting the expenses, they affirmed, exceeded seven thousand *tomans*. One *batman* of white naphtha is sold here for one *shai*, that is, about the eighth part of a rix dollar; one of black naphtha for a little less. But I will not guarantee these figures of price and yield, because, being then ignorant of the Turkish language, I used for inquiry an interpreter who was not sufficiently versed in the vernacular of the region. I saw black naphtha floating on a small stream in the District Ruduun of the Kirman Province, also in a torrent of the Shirwan Province (this one that we are concerned with now), a torrent that enters the river Kuur from the north. In this, it was so abundant that it might be gathered, if the peninsula did not supply it so richly.

* * * * * * *

BITUMINOUS, GASEOUS LAKE.

The next day (January 8th) [1684], we were roused with the first light and led to a new prodigy, which in their language they called the "naphtha refinery," situated not far from the inn, in the same series with the springs, and as it were in line with them. There was an elevation raised you may say into a hemisphere, but a little depressed, and rising not more than three fathoms above the level of the ground, with an oblong round base. On its summit was seen a lake, in circuit, as I took it by conjecture, about fifty steps; for the marshiness of the place and the danger of the shore's sinking in, or fear did not permit going around it. The water had a briny taste, and to the sight a blackish color, and resounded with a perpetual tumult, not only from continually boiling waves on the surface, but more particularly from the movement of boiling liquids in the lowest and apparently the remotest depth of the abyss, a tumult that kept strangers intent with horror and in suspense on the margin of the lake; the foot, too, trembled, for a horrid sounding abyss was felt to be beneath it. With the bubbles arose not seldom a scum of earthy substance, dark and blackish, that they said was refuse of naphtha; of this, driven as it was continually to the shore, and issuing as it did with the larger bubbles through a long term of years, the elevation itself seemed to have been formed; as both the shape indicates that arises from such accretion, and the substance bears witness, that is mixed and cemented together of earth and bitumen. Several little fountains surrounded the lake and were large enough to hold a finger or the hand. I counted twenty-five of them on the top and fifteen lower down, all pouring out water clearer than any crystal, differing too very greatly among themselves as well as from the water of the marsh in taste, especially in stronger or milder saltness; as the neighboring inhabitants particularly showed us among the remarkable things. The lake, although it was perpetually boiling with bubbles emitted from the bottom, nevertheless yielded its own water in quite small quantity, a fact that I observed likewise in regard to many of the small fountains, in which the water did not seem so much to gush out as merely to be agitated by the issuing gas. I add the following from the oral philosophy of the rustics who were over the works: All the naphtha flows forth by subterranean channels from the innermost bowels of the neighboring mountains; and while it flows through the laboratory of this swamp, it separates its refuse and is refined, and otherwise it would produce a thicker, useless product in the wells where it is extracted; whatever slips past these wells without being intercepted is filtered by a longer space into the appearance of a transparent and very pure liquid, which, under the name of white naphtha, shows itself in the remoter place that we looked at yesterday; while another part of the same, and that the greatest, in the Field of Vulcan, as if it had fallen upon a blazing wick, nourishes smoke and perpetual flames, that would quickly burn out there if all the fuel could be intercepted on the way.

ASPHALT.

Hence, mounting our horses, after midday we came to the fifth wonder, namely, a remarkable hill of a black, thick, bituminous liquid, which it poured forth. It was situated in a moist, depressed tract of land, that had the appearance of a broad lake, but one of stagnant water. Through this rapidly flowed a rivulet of a palm in depth and five steps in width, purer than any crystal, but most intensely salt, washing the very base of the hill with a moderate circuit. The hill had in front a round shape, and the hight (as I conjectured from its looks) of twenty fathoms or more. The lowest part was of red mud mixed with sand or gravel; the middle part was a combination of shells of various kinds with earth; the uppermost part was a purer mud covered with a green sod; the top was adorned with a fertile field, extending by the narrow surface of the sloping ridge to the upper neighboring plains. The liquid, which they call cruder naphtha, trickling forth from the very top in many places, not only did not overflow the whole face of the hill, but by no means reached the base toward the south and west, because in its descent the ground absorbs part, and a part, too, is hardened by the sun's rays and incrusts the hill. The country folks dig up this material, and carry it in two-wheeled carts to distant villages, to burn for heating baths. It is a substance that makes a blaze and keeps afire a long time, black and tough, like pitch; within, if you break it, reddish-black and earthy.

A MUD VOLCANO.

After looking at the hill, we hastened without delay to see another phenomenon in the northern end of the peninsula, where we arrived with three hours' slow riding; first through deserted and uneven plains, then soon through a hilly country, and at last across a depressed plain notable for a couple of large lakes. What filled the mind with admiration was a hillock of a conical shape (if it had an apex) raised to eight fathoms in vertical hight, bare of all grass and turf, rough and uneven; from the top of which moist clay, such as is worked by the potter's hand, issued, being protruded by an extremely slow and scarcely perceptible movement; and when it had risen to the moderate hight of several spans, unable to sustain itself, it flowed down on every side, but particularly toward the south, as if natural inclination directed it that way. For here, the declivity was abrupt, and there was a great pool of earth of cushion shape, which both received the earth that flowed forth and with the falling showers that washed it out sent it forward into the neighboring plains. The hillock, which they called *Jugtopa*, having at a distance the appearance of a small tower, was situated on a somewhat high elevation of the ground, which in this place showed mud of a slightly reddish color, and, further on, a somewhat black soil, and fields that were not unsuited to the plow. The clay, I say, issuing from this source, when it had been dried on the edges by the sun and in many years had settled down, seemed to have formed in the process of time the tower-shaped heap; through the central cavity of which either the subterranean forces of fires and gases, or even the heavier weight of the overlying earth and hills upon the thin mass constantly ejected this earth. The inhabitants of the neighboring village Sishaan said the clay was not always ejected with the same steady movement; that it often burst forth with violence and was thrown out to a hight; that they had heard from their parents that it sometimes sent out huge stones mixed with earth, which, being tossed far out and high, had threatened to cut off egress from their village, although it was distant a quarter of a league, so that they were not allowed to live there safely, until by the advice of the magians they had pacified the wrath of the impelling subterranean Æolus with the blood of a sheep slain at the hillock's jaws. In order to examine the matter more thoroughly, with the safe guidance of a man that went before and cut steps, we explored up to the very summit, not without risky inconvenience; for the ascent was precipitous and everywhere slippery, and the material for us to tread on was fragile and friable. Around the summit, we found the tracks of men who had been there before us; also a cavity cut out by the hand of man, where a single spectator could safely stand; goat-dung, too, by what chance brought there I know not. The size of the issuing clay was not too great for me to encircle it with three spans. I took the risk of riding around the base, in truth not without danger; for on the southern side which slopes down into the pool, when I had spurred the horse on, I like to have been submerged with the horse in the abyss of softer clay accumulated there for a long time; the crust broke that treacherously concealed the swamp.

SALT-WORKS.

There remained the last sight to be seen with eagerness, namely, the salt-works half a league distant, not far from the king's highway, at the entrance to the peninsula. We entered on this road afoot, as we had sent the beasts forward to feed. It was an oblong round lake of nearly a league in circuit, of little depth, surrounded by four rather small villages that were inhabited by a rabble of shepherds, who also work the salines. The bottom extends with a scarcely perceptible descent a hundred steps and more from the shore, all (until the brine is reached) free from liquid, flat, hard, clayey, and slippery. This brine, of which the greatest depth was said to be three feet, produces an abundance of the most splendid salt, not elaborated by artificial means, but solely by the heat of the sun; in fact, while its rays draw out the fresh water as lighter and superfluous into the air, the liquid remains heavy with salt, which, condensing into what you might call snowy layers, goes by degrees to the bottom and subsides there. So from the bottom by means of a wooden rake it is scraped together, and then is taken out with a shovel, and placed upon four-wheeled carts that carry it off. When it has been carried to the eastern shore, it is arranged in cubes of definite size, and is beaten with beetles while carefully heaped together, so that the remaining moisture may be driven out and sufficient firmness given to insure the heaps against accident or any atmospheric injury. The hired laborers had stopped at the time of our arrival; in order, nevertheless, to gratify our desire, they sent back one carter with a horse not yet unharnessed to the place where they had left off collecting; and he, in our sight, with short delay and without any trouble, filled the vehicle he stood in with the whitest salt; which, when it had been carried to the shore, we found hardly to drip noticeably any more, because part of the abundant moisture had fallen from the drawing apparatus and part from the cart. The cubical form of the heap pleases them because thereby the quantity collected can be more exactly known, and an estimate arrived at about the sale and carriage. There were forty heaps, at a distance counterfeiting the appearance of a village, if the color were not different; for they have the shape and size of villagers' little houses. They said that a cube was collected each day; in summer one, in winter hardly half a one, because then, on account of the abundance of moisture, the salt gathers more sparingly. It is carried away on two-wheeled carts and on the backs of camels, partly to the port of Baku, to be sent abroad by sea, and the rest in various directions through the provinces.

PROPOSED MINING EXHIBITION.—Steps are taking to hold an International Mining Exhibition in London next year. The arrangements are in the hands of Mr. A. Zeehandelaar, who was awarded a diploma of honor at the Amsterdam Exhibition for his display of minerals from over four hundred mines in Utah, Montana, and Idaho, and it is intended as far as possible to bring together every thing appertaining to mines and minerals in the world.

THE EVANS SAFETY-GUARD.

Written for the Engineering and Mining Journal by Joseph M. Locke, C.E., M.E., Salt Lake City, Utah.

The frequent occurrence, of late, of steam-boiler explosions has aroused considerable interest in the various methods devised for their prevention; and the article in this JOURNAL of August 18th, 1883, upon "The Schwartzkopff Safety Apparatus for Steam-Boilers," by C. A. Stetefeldt, suggested to me the advisability of drawing attention to the Evans Safety-Guard, a device invented by the late Cadwalader Evans, of Pittsburg, Pa., and patented in the decade between 1840 and 1850. This device has apparently been forgotten, although the existence of the present steamboat laws is largely due to the discussions it aroused by the vindictive opposition it met from large numbers of steamboat engineers. Like the apparatus of Schwartzkopff, it provides against—1st. Undue pressure. 2d. Low water-level. 3d. Firing empty, and subsequently injecting water on the heated flues and sheets. 4th. Retarded boiling, that is, the condition in which the water reaches a higher temperature than the pressure indicates.

The resemblance is further carried out by the use of an alloy fusing at a predetermined temperature; but the method of using the alloy is entirely different, as shown by the accompanying sketch, which represents a steam-boiler and ordinary safety-valve, with the device of Evans attached.

A is a boiler with flue *B*. A part of the head is represented as cut away, so as to show the interior arrangement (which is drawn in section). *C* is the lever of an ordinary safety-valve, with fulcrum at *D*, having a counterweight *E* on one end, the other end being bent down and forked to receive the sheave *F*. *G* is a valve and seat of ordinary construction. Through the top of the boiler *A* is inserted a tube *H*, with lugs *J J'* in the inside, and the lower end closed and resting on the flue *B*. Within the tube *H* is a spindle *K*, having near its lower extremity projecting wings *L L'*. Upon the top of the spindle *K* is firmly secured the spool *M*, to which is attached the chain *N*, which chain *N* is wound two or three turns upon the spool *M*, then carried over the sheave *F*, and finally to the end is attached the weight *W*, which is supported a short distance above the shelf *S*. The lower end of the tube *H* is filled to a little above the lugs *J J'* with an alloy (represented in stipple) which will melt at such a temperature as corresponds to the pressure desired to be the maximum to which the boiler should be subjected. The action is as follows:

I. If the weight *W* is less than is requisite to hold the valve *G* closed at the maximum pressure, then the valve will act as an ordinary safety-valve when the pressure in the boiler reaches a point where it exerts a force on the valve *G* slightly above the counteracting effect of the weight *W*.

II. If the weight *W* is too great for the pressure on the valve *G* to raise it at the pre-arranged maximum pressure, then, upon the pressure ariving at that point, there will be the corresponding rise of temperature and consequent melting of the alloy in the tube *H*, in which condition the weight *W* acting through the chain *N* upon the spool *M* will freely rotate the spindle *K* (as the alloy being melted no resistance is offered by the lugs *J J'* and wings *L L'*), the weight *W* will descend to the shelf *S*, thus relieving the valve-lever of all weight; then the counterweight *E* will throw the valve open. Immediately upon the reduction of pressure within the boiler, there will be a corresponding reduction of temperature and consequent solidification of the molten alloy, resulting in immovability of the spindle *K*. Hence the weight *W* can be raised and the chain *N* wound a turn or two upon the spool *M*. Then every thing is again in order.

III. During the firing of the boiler, whenever the water becomes so low as to expose the top of the flue, the alloy becomes molten and the valve consequently flies open. Any attempt to close it by winding the chain upon the spool *M* will fail, as the alloy remains fluid until the flue is allowed to cool, which will generally require the fire to be drawn.

IV. An attempt to steam without a proper supply of water will be futile for reasons stated under III.

V. In those peculiar cases known as "retarded boiling" (in which the water becomes heated above the temperature corresponding to the pressure in the boiler), such a condition is indicated and calamity averted by the fusion of the alloy, and consequent opening of the valve prior to the accumulation of such an amount of heat within the water as to endanger the safety of the boiler by its sudden liberation in the form of steam.

The successful action of the apparatus in the cases III., IV., and V. is in no way affected by the weight *W* being heavy or light.

If an electric alarm, in addition, should be thought desirable, then a break-circuit ratchet could be put upon the spindle *K*, which would actuate the alarms whenever the device is called into action.

From the preceding, it appears to me that the old device of Evans has, over the more recent apparatus of Schwartzkopff the following advantages:

1st. It not only gives the alarm of danger, but at the same time automatically actuates the safety-valve so as to prevent an explosion.

2d. Being purely mechanical in its action, no battery is required.

3d. The apparatus may be brought into action an infinite number of times without requiring the removal, replacing, or renewal of the alloy.

4th. In case of deficiency of water, the valve can not be closed until the boiler is cooled down, so as to admit of water being added with safety.

5th. Neither steam nor water enters the chamber containing the alloy, nor comes in contact with any of the moving parts of the device.

OIL IN CALIFORNIA.

J. W. McKinley, writing to the Pittsburg *Dispatch*, gives the following account of the California oil-field at Newhall:

On the edge of the town, is located the refinery of the company, connected by pipe-lines with the wells a few miles distant. Leaving Newhall, we drove to Pico Cañon, the principal producing territory of the region. As we approached, we saw, away up on the peaks, the tall derricks in places which looked inaccessible; but no spot is out of reach of American enterprise and perseverance. In one of the wildest spots of the cañon, about thirty men were making the mountains echo to the strokes of their hammers upon the iron plates of a new 20,000-barrel tank. Along the cañon, are scattered the houses of the employés of the company, most of whom have recently come from Pennsylvania. Near one of the houses, was a graded and leveled croquet-ground with a little oil-tank on a post, for lighting it at night. Farther up, we came to a cluster of producing wells, with others at a little distance on the sides of the mountains, or even at the top, hundreds of feet above our heads.

The first well was put down about eight years ago, but more has been accomplished in the last two years than in all the time previous. One well which we visited has produced 130,000 barrels in the last three years, and is still yielding. There have been no very large wells, the best being 250 per day, and the average being about ninety barrels, but they keep up their production with scarcely any diminution from year to year. Drilling has been found difficult, as a great portion of the rock is broken shale lying obliquely. The tools slip to one side very easily, and a number of "crooked holes" have resulted. One driller lost his tools altogether in a well, and finished it with new ones. The cost of putting down a well is from $5000 to $7000, depending upon depth, etc. Most of the wells are from twelve to fifteen hundred feet, but some have yielded at a much less depth. One well of 270 feet depth produced 40 barrels per day for about three years, has been deepened, and is now yielding even more. Another one of 800 feet is said to have produced 200,000 barrels in the last five or six years. Drilling has been very successful in striking oil in paying quantities wherever there were indications of its presence.

The Pacific Oil Company now has 27 wells producing or drilling, and during the last two years has been rapidly widening the scope of its operations. It has now from thirty to forty miles of pipe-lines, and is preparing to lay twenty miles more, to connect its land with ocean shipping at Ventura. The producers of California have a great advantage in their proximity to the ocean, which gives them free commerce with the outside world. Crude oil is now sold at $3 per barrel in Los Angeles, and the oil companies are making immense profits. There is a very large amount of oil territory as yet undeveloped, and a rich reward awaits enterprise in these regions. In the Camulos District, which lies west of the San Fernando, are even stronger surface indications of oil than there were in the Pico Cañon. We first went up the Brea Cañon, in which are numerous outbursts and springs of oil. Ascending the mountain west of this cañon, we could plainly see the break in the mountains crossing from the San Fernando through this district to those beyond which have been developed. A couple of miles farther west, the Hooper Cañon stretches back over two miles into the mountain, and is full of oil. Great pools of oil fill its water-courses that are dry at present. Hundreds of barrels of oil must be wasted away and evaporated during a year. A well put down only 90 feet by horse-power struck light oil in considerable quantity, and, had it not been for the death of one of the owners and the consequent suspension of operations, would doubtless have yielded in large quantities at the depth of a few hundred feet.

The mountainous territory between these two cañons will probably in a few years be the scene of great activity. In the Little Sespe District, a few miles west of Camulos, a 125-barrel well was struck at 1500 feet recently. The Santa Paula region, a little farther west, is also yielding large profits to the parties developing it.

THE LAW AS AFFECTING MINING AND METALLURGICAL INTERESTS.

Motion to Dissolve Temporary Injunction against Removal of Ore from Disputed Ground.—A case has just been decided by Judge Church, in Dakota, which is of considerable interest. The case was that of the Richmond Silver Mining Company *versus* John A. Davey *et al.*

The premises in question are situated in Bear Butte Mining District, Lawrence County, Dakota, on the northerly slope of what is known as Custer Hill. Nearest to the bottom of the slope and therefore farthest north, is the defendants' claim or location called the Sitting Bull, the longitudinal course of which is substantially east and west; parallel with and adjoining this on the south is the Tiger Tail claim or location, also the property of the defendants; then follow in the order named, successively, the Surplus, Fraction, and Silver Terra locations, the property of, or at least claimed by, the plaintiffs in these three actions respectively, all of which are located substantially parallel with the Sitting Bull.

The Sitting Bull claim was entered for patent January 8th, 1883; the Silver Terra, May 8th, 1883. None of the others has as yet been entered for patent.

The plaintiffs allege that they are the owners and entitled to the possession of the three several claims above named, and that, at the time of the entry by defendants, they were in the actual possession thereof, and had expended large sums of money for their development, and were and are contemplating the erection of extensive mills and other works in connection therewith.

The defendants, having started a tunnel upon their Sitting Bull claim, have extended the same, with numerous collateral drifts, in a direction somewhat east of south, across their Tiger Tail claim and the Surplus and Fraction claims of the plaintiffs, until, at the time they were stopped by the injunctions, the face of the tunnel had reached a point slightly within the northerly side-line of the Silver Terra location drawn vertically downward. This is the main working tunnel of the defendants, and from it, as the plaintiffs allege and the defendants do not deny, the defendants have extracted a very large amount of valuable silver ore, which they have milled and reduced in their own works located near by. At the time the injunction was granted, this work was vigorously prosecuted by defendants.

The defendants also have another tunnel started on their Sitting Bull claim at a point some distance west of the main tunnel, the workings in which have been extended across the Sitting Bull and Tiger Tail to a point slightly within the northerly side-line of the Surplus, extended vertically downward.

Upon learning of this action of the defendants, the plaintiffs took steps to arrest the work. Actions were begun against the defendants to recover possession of the ground upon which they had entered, and for damages, and orders were granted requiring defendants to show cause why an injunction should not be granted restraining them, during the pendency of the actions, from the prosecution of their work in the disputed territory.

The demand for a dissolution of these injunctions appears to rest mainly upon three propositions:

First. That plaintiffs have failed to show affirmatively the performance by themselves, or those under whom they claim of the acts necessary to constitute valid mining locations under existing laws and regulations, and that therefore they have no standing in court to challenge the acts of the defendants, even though they be mere trespassers.

Second. That before the plaintiffs can question the defendants' right to mine and remove the body of ore in which they have been working, they must also show a continuous vein or body of ore extending to the ground in controversy, and the top or apex of which is within the surface-lines of their location, drawn vertically downward.

Third. That defendants have themselves established the existence of a continuous vein or body of ore, the top or apex of which is within the surface-lines of their Sitting Bull location, and which extends without interruption to the ground in controversy; and that defendants by their tunnel workings were following this vein, as they were entitled by law to follow it, in its departure from the perpendicular, or as commonly expressed, on its dip (which is its deflection from the horizontal), until they were stopped by these injunctions.

Judge Church's discussion of the second and third points is of particular interest.

The common law rule is familiar; the ownership and possession of the soil extended to the center of the earth, and "usque ad cœlum," and included every thing upon its surface and within its bosom.

It is conceded by defendants' counsel that the possessory rights of one having a valid mining location are co-extensive with those acquired by patent.

We find that the thing, the substance of which the U. S. statute treats, is, "lands valuable for minerals," and that it is for the disposition of these "lands" that provision is made in chapter vi. of the Revised Statutes. It is the "lands" in which mineral deposits are found which are "open to purchase."

It is "land claimed and located for valuable deposits" which is the subject of application for patent, and where the patent of the U. S. issues, it is for the "land" at so much per acre. The definition of "land" given in our territorial statute is concise: "The solid material of the earth, whatever may be the ingredients of which it is composed, whether soil, rock, or other substance." In the absence of any thing to the contrary in the statute, I think it might well be concluded that one becoming the owner or possessor of any of these lands would hold them with and subject to all the incidents of ownership and possession at common law.

It should be borne in mind that, before the enactment of any statute recognizing and regulating his possessory rights, the mining locator, as between himself and the United States, was technically a mere trespasser upon the public domain, and that, even although he might have conformed in his location to the rules and customs adopted in the mining districts in which his claim was situated, yet, so far at any legal right existed to hold his claim against a new-comer, that right rested upon possession merely; hence the statute. United States Revised Statutes, p. 910.

The government, however, having, in pursuance of its policy of encouraging the discovery and development of its mineral wealth, long tacitly recognized the possession of the miner has now by statute not only given an express license to those establishing their possession in the prescribed method, and provided a way by which the locator may become the owner in fee of the land embraced within the lines of his claim, but has also declared that such locators "shall have the exclusive possession and enjoyment of all the surface included within the lines of their location, and of all veins, lodes, and ledges throughout their entire depth, the top or apex of which lies inside of such surface-lines extended downward vertically, although such veins, lodes, or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side-lines of such surface locations."

This statute undoubtedly introduced an important modification of the common law rule; it gives to the proprietor of a vein a right unknown to the common law, the right to pursue such vein beyond his own lines, outside of that particular segment of the earth embraced within the lines of his claim extended vertically downward, and it is therefore to that extent an enlargement of his common law right. But on the other hand, inasmuch as the same right is granted to every locator under the statute, each holds his possession subject to the same right in others, and is therefore liable to have his land entered by an adjoining proprietor pursuing his vein in its course beyond his own side-lines; and to this extent, therefore, his common law possession is abridged.

Two points can not fail to be noticed in this connection;

First. That this enlargement of the common law possessory right is incident only to a claim located in the manner provided by law; and

Second. That the exercise of such right operates to the abridgment of the possession of every tenement penetrated or intersected by a vein having its top or apex in a superior tenement.

Such I understand to be the effects of the statute. I am unable to see that in any other particular the rights of possessors of mineral lands differ from those of other lands.

I must therefore conclude that one holding a mining claim by mere right of possession, while on the one hand not receiving that enlarged power incident to a valid mining location, and on the other hand being subject to intrusion by the lawful proprietor of any vein which may be found in its course downward to penetrate or intersect his claim, holds his claim in other respects with and subject to the incidents of possession at common law, and may defend his possession of the surface and of that segment of the earth included within the surface-lines extended vertically downward, with all that it contains, against every one not claiming under superior title.

This disposes of the first two propositions above stated and brings me to the consideration of the third.

The defendants undertake to justify their intrusion upon the plaintiffs' ground by virtue of their alleged proprietorship of a vein having its top or apex within the surface-lines of the Sitting Bull location and extending in a continuous body to the ground in controversy.

At the time these motions were argued, no answers had been filed. There is no denial, therefore, by answer, nor, indeed in the affidavits submitted, of the equities of the plaintiffs' complaint.

Their prior possession of the ground in controversy (under the views I have above expressed), the entry by defendants, and the injury and damages complained of are not denied.

Defendants seek to justify under a right conferred by statute, depending for its lawful exercise upon the existence of certain facts which they must establish affirmatively by preponderance of evidence.

This is clearly new matter, and although the affidavits by which it is sought to establish the necessary facts are very voluminous, yet they are met by an equally imposing array of depositions on the part of the plaintiffs.

In my judgment, as far as I am now able to apprehend the nature of this controversy, the question thus raised is the one upon which the essential rights of the parties depend.

To determine it now would be, in effect, to determine the whole controversy. In such cases, the well-settled rule and practice of courts of equity forbid the dissolution of the injunction by which the property is preserved *in statu quo* until the trial. I do not remember that this point was discussed on the argument, but I observe that defendants' counsel in their brief contend that while this was the old rule in equity, it has been entirely changed by the code.

Besides, I am unable to say that a consideration of all the testimony satisfies me of the existence of those facts upon which the right claimed by defendants depends. Even taking the affidavits submitted upon the part of the defendants by themselves, some facts are therein disclosed which do not seem to me entirely consistent with the theory that they are pursuing a vein which, departing from the perpendicular, extends in its course downward beyond the side-lines of defendants' claim into the ground of the plaintiffs.

But recognizing the unsatisfactory character of testimony thus adduced, I can not but feel that justice to both parties demands that the final hearing be entered upon unembarrassed by a previous decision of this important question.

The character of the injury complained of, too, threatening as it does the entire destruction of the estate in controversy, would upon equally well-settled principles demand a continuance of the injunction.

I am not unmindful of the considerations, so strongly urged, of possible injury to the defendants from the continuance of these orders, but these considerations can not justify a disregard of settled principles of equity jurisprudence. The peril to the plaintiffs must also be considered, and it should be observed that, as disclosed by the plaintiffs' affidavits and not denied, the defendants have prosecuted this work with full notice that their right to do so would be contested.

These motions were finally submitted September 25th; on the 26th, I left for Yankton to attend the fall term of the Supreme Court, and since my return have been almost constantly engaged in the trial of jury cases. Amid this multiplicity of duties, I have given to these motions all the time and consideration practicable, and have come to the conclusion that they should be denied.

Iron Ore Contract.—The Cleveland *Western Machinist* prints the following:

A decision of considerable importance to producers and consumers of iron ore was rendered the past week by A. J. Ricks, Esq., appointed by the United States Circuit Court of this city to hear the case of the Florence Mining Company against the Receiver of Brown, Bonnell & Co,

Digitized by Google

From the evidence adduced, it appears that the Florence Mining Company, as vendor, contracted on the 13th of February, 1882, with Brown, Bonnell & Co., as vendee, to sell to the latter 30,000 tons of iron ore of its standard quality, deliverable at Cleveland and Ashtabula during the season of navigation of 1882, on the docks of the New York, Pennsylvania & Ohio and the Lake Shore & Michigan Southern railroads respectively, as nearly one sixth of the total quantity per month as practicable, the ore to be paid for at the rate of $5.75 per ton in eight equal payments of $21,562.50 each, payable on the 15th days of May, June, July, August, September, October, November, and December, 1883, respectively, in cash, making in all $172,500. Under this contract, the vendor had delivered to the vendee, prior to February 19th, 1883, 20,762 tons of the ore specified. On February 20th, 1883, Brown, Bonnell & Co. went into the hands of a receiver. On the day preceding, the vendor temporarily suspended shipment of ore, under fear of the insolvency of the vendee. Up to this time, the contract had been complied with by both parties, and 9238 tons remained undelivered. The vendor failed to deliver any part of the balance, because of the insolvency of the vendee, but claimed to have had the ore ready for delivery, and would have so delivered it had the vendee made any demand for it. The vendee, however, made no such demand and plainly indicated its desire to rescind the contract. Under these circumstances, it was the privilege of the vendor either to concur in the vendee's wish to end the contract or to insist upon its fulfillment. It claims to have done the latter, and asks for the full amount due under the contract.

The turning point of the Special Master Commissioner's decision is upon the fact that the sale was made on credit and not for cash. If it had been for cash, the vendor would unquestionably have had the right to make tender for cash, and on refusal to accept and pay cash on the part of the vendee, the vendor could have sold the undelivered ore at the market price at the time of the breach, and have offered to credit on vendee's notes the sum realized; but the vendee having contracted to pay for the ore in its notes, the vendor, if it intended to insist upon enforcing the contract, should have tendered the ore on credit, according to contract. Having failed to do so, the Master is of the opinion that the vendor elected to concur in the recision of the contract, as the vendee, by its conduct, may fairly be held to have offered to do. The issues were therefore found with the defendant.

THE POETSCH SYSTEM OF SINKING THROUGH QUICKSAND.

We have repeatedly alluded to the Poetsch system of sinking through quicksand, and the interest taken in it in Europe warrants the reproduction from the *Colliery Guardian* of the following account by the well-known writer on mining subjects, Mr. George G. André, who says:

I have been so often questioned of late concerning my opinion of the merit of Poetsch's system of sinking through quicksands that I have thought it desirable to form one as speedily as possible. For it must be confessed that, in common with many others, I had regarded the invention as deserving of but little attention. One is too apt to view in this narrow light what may be described as deviations at right angles from the ordinary ways of experience. As long as new methods of procedure run parallel with or diverge but slowly from these beaten paths—in other words, so long as they differ from known and well-tried methods only in the details of their application, or in the manner of their execution—all are ready to lend an eager ear to the inventor, and to give hasty credence to his exaggerated promises. But when a system of working which, like that of Herr Poetsch, is novel in principle and wholly dissimilar in all its features from every thing that has gone before, the originator soon discovers, to his cost and chagrin, that he has to deal with ears that are deaf, and with heads that have a propensity for shaking. Poetsch's system has been described in some of the technical journals solely for the purpose of holding it up to ridicule, and in others to afford the writer an opportunity for exhibiting his cleverness in discovering insuperable difficulties in the way of its application. That the scheme was something more than the dream of a visionary man was, however, made evident by the announcement a short time ago that the system was to be put to the test of actual practice at the important mine known as the "Grube Archibald," and by the rapidly growing interest in the matter, which prompted the questionings to which I have already alluded. To convince myself by personal observation of the truth concerning some contradictory reports of the success attained at this first trial on a practical scale, I resolved to see without delay what was really being done at "Grube Archibald." The evidence there obtained upon the spot is sufficient to remove all doubts upon certain points, and goes far to show that a very important addition has been made to the art of mining.

For those readers who may not yet have heard of this system, it will be well to describe it briefly. It consists, then, in freezing the water through which the shaft has to pass, and in excavating the frozen mass by the ordinary means. In this way, not only is the sand and water taken out in solid and hard blocks, but a walling of ice about three feet thick is left around the excavation to keep back the water. This novel idea was generally acknowledged to be exceedingly clever, and sound in principle, but its practicability, and even the possibility of carrying it out at all, were doubted. This point has now been set at rest by the results of the trial at "Grube Archibald." In about fifteen days, the ground covered by the area of the sinking, and 30 inches around, was made solid with ice, and so firmly was it frozen that it was hard to break up the blocks that were taken out; no scratch could be made upon them with the finger-nail. In commencing a sinking over a known water-bearing stratum, the shaft is laid out, and carried down to the sand, of a diameter slightly larger than what is intended as the ultimate size. A circle of small bore-holes, about three feet apart, is put down a little outside the true shaft, that is, just within the sides of the shaft as it will be when excavated to its required diameter. A second circle of bore-holes inside the first, and consequently within the area to be excavated, is next put down, and a single hole in the center completes the set. As far as the character of the ground will permit, these holes are bored simultaneously with the sand-pump. Over the holes, and raised a little above the bottom of the sinking, is an annular distributing tube, from which small copper tubes provided with cocks descend to the bottom of the bore-holes. At bank is a Carré freezing-machine which, by the ammonia process, produces a high degree of cold. Heat is abstracted from a concentrated solution of the chlorides of magnesium and calcium, the freezing-point of which lies between 35 and 40 degrees Centigrade. This solution, at about a temperature of 25 degrees Centigrade, is driven by a small force-pump into the annular tube, whence it flows down the copper tubes to the bottom of the bore-holes. It then ascends in the lining tubes and passes back through a common ascension-pipe to the machine. In this way, a constant circulation is kept up. It will be seen that while ascending in the bore-holes this cold solution abstracts heat rapidly from the water in contact with the outside of the lining tubes, and that the greatest action takes place at the bottom. This gives a gradually increasing mass of ice from the top to the bottom of the bed—that is, a truncated cone of ice in the watery stratum, a circumstance happily in accord with the increasing pressure of the water. When the ground has been sufficiently frozen, a fact to be ascertained by boring, the work of sinking begins. It consists merely in excavating the solid mass of ice and sand, and in building up the brick or iron lining (walling or tubbing) inside the ice-bound sides of the shaft. As there can be no influx of water, the work presents no difficulty. For security, the circulation of the freezing liquid is kept up in the outer circle until the shaft has been sunk completely through the quicksand. At the "Grube Archibald," the system could not, unfortunately, be carried out in the most convenient manner; for the sinking was not commenced from the surface, but from the bottom of an already existing shaft 100 feet deep. The shaft is rectangular, 10 feet 4 inches by 14 feet 6 inches, and the quicksand bed is 13 feet thick. All the bore-holes in this case, twenty-three in number, have necessarily been placed inside the shaft, where they are seriously in the way of the sinkers. But in spite of this unfavorable circumstance and some other disadvantages attendant on all first attempts, enough has been accomplished to place the practicability of the system beyond doubt. It is yet too early to compare the cost with that of the ordinary methods; but it is easy to see that when there is much water to be dealt with, Poetsch's system must be an economical one; it certainly affords a high degree of safety in working.

This matter of dealing with water recalls to my mind a dam lately constructed in a coal mine in Belgium for the purpose of shutting off a large body of water that had broken in from some old workings. This dam is remarkable only for its good design and excellent construction. It consists of three semicircles of bricks, each 3 feet thick, and separated one from another by 4 inches of clay puddling. This constitutes the dam proper; but above it, that is, on the water side, is a stopping of clay, 8 feet thick, and behind it, as a support, there are 33 feet of rubble masonry. The character of the Belgian coal-fields renders damming of very frequent application in the mines, and numerous good examples of these constructions are to be met with.

A TEST OF THE NOTEMAN ROTARY ENGINE.

Prof. Robert H. Thurston, of the Stevens Institute of Technology, Hoboken, N. J., has addressed to Messrs. Ledoux & Ricketts, of this city, an abstract of a report upon the performance of the Noteman engine, from which we take the following: The tests have been unusually complete, and, although not in precisely the same manner as I had originally intended, have furnished all essential facts relating to the efficiency of the engine, and its value, as compared with reciprocating engines of equal power. The engines tested, and those inspected by me previous to the tests, are generally well made, and capable of doing the work for which they are intended. The efficiency of the engine from which the data to be given were secured is somewhat impaired by defective fitting, as shown on inspection after test, and this being remedied, the machine should do even better than here indicated.

The tests consisted in the determination of the gross and net power of the engine by the indicator and dynamometer, the consumption of water and steam, the friction of parts and of the engine as a whole, and the action of the inertia in the production of unbalanced stresses. The variation of the rotative effort at the shaft was also determined and its influence upon the size of the fly-wheel needed.

After these points had been worked up, the engine was compared with reciprocating engines of similar power, to ascertain their relative standing, the points compared being the economy, the smoothness of motion as affected by the variation of rotating effort, the amounts of clearance, the balance, and the liability to loss by cylinder condensation. The performance of this engine is also compared with that of other rotary engines, tested under my order as chairman of a committee of the Board of Managers of the Exhibition of the American Institute having charge of the Machinery Department, in the year 1873, of which tests the results were published later in London *Engineering*, and in *Spon's Dictionary*. These determinations and comparisons lead to conclusions which may be briefly summarized as below. The report in detail will require some time for preparation.

The engine tested was rated at ten horse-power. It was tested under 80 and under 60 pounds steam pressure. The indicated and the dynamometric power, at 60 pounds pressure by gauge, were respectively 14·8 and 12·4 horse-power, showing a loss of 16 per cent by friction in the engine. The consumption of water and steam amounted to 656 pounds, or 43 pounds per indicated and 50 pounds per dynamometric horse-power per hour. The speed of the engine was made, in this trial, 350 revolutions per minute. It ran smoothly and evenly, and gave no trouble from heating, or any other cause, during a run of two hours. Every thing was in good shape at the close of the trials, and the engine in as good condition to continue its run, at the excess of 50 per cent above its rated power, as at the beginning. The indicator diagrams taken were quite similar in their general proportions to those obtained from other small engines of usual forms and of the same power. The point of cut-off was not far from half-stroke, and the lines of the card were good, from the beginning of the steam line to the end of the expansion curve. The cushion line has a peculiar form, which comes of the special method of terminating the exhaust, which is due to the construction of the engine. It has no important effect upon the efficiency of the machine. In consequence of the variation of the volumes of cylinder exposed to action of the steam, throughout the stroke, the real ratio of expansion is about two thirds the apparent

Digitized by Google

ratio, or 1·4, instead of 2. The weight of the steam accounted for by the indicator is about 75 per cent of that actually measured at the tanks in which the exhaust was condensed. The cylinder condensation thus amounted to 25 per cent of the total weight of steam entering the engine.

In making a comparison of this engine with others, it is found that its consumption of steam, and consequently of fuel, is vastly less than either of those of which the results of tests were published as above. It demanded but one third as much as the best of those engines, and but one tenth as much as the least economical of that set. Its greater power will account for a part of the last enormous discrepancy, but not for the superiority of the Noteman to the most economical, which was of similar rating and of two thirds the actual power. In comparing the Noteman with a reciprocating engine, one of the latter class was selected which was known to be of good repute and to be able to run at high speed with safety. It was six inches in diameter of cylinder and of eight inches stroke of piston, and at the same speed of revolution, cutting off at the same actual point of cut-off, that is, having the same real ratio of expansion, would develop the same power. The engine was judged to be one which could be relied upon to do its work under these assumed conditions. It was one of the best of its class. The clearance and "dead spaces" in this engine were about one fourth, or less, than those of the rotary. The loss of steam is correspondingly greater in the latter; but this loss can, and should, be very much reduced, and can be made comparatively unimportant by rearranging the cut-off valve in such manner that the valve-seat shall be brought down close to the cylinder-port.

Comparing the areas of internal surface productive of cylinder condensation, as measured up to the point of cut-off, it was found that the rotary had 15 per cent greater area than the reciprocating engine. It would be expected that it would be at some disadvantage in this respect; but this is not indicated by test, as the Noteman engine exhibited very much less loss in this direction than we are accustomed to find in the small reciprocating engines which are fairly comparable with it. The loss from this cause in larger reciprocating engines, as constructed by the best makers, very rarely falls below that observed in this little rotary.

On studying the action of the rotary with respect to uniformity of moments producing rotation of the crank-shaft, it was found that it has no "dead-center" at all, and that its action upon the shaft is very much more uniform than can be that of any single reciprocating engine. This difference is two and a half to one in favor of the rotary. It therefore indicates that the latter would require a fly-wheel less than half the size of the common form of engine, or with the same weight of wheel, it would regulate correspondingly closer. The same superiority is apparent in the comparison with a view to determine the tendency to shake the engine loose from its foundation. The superior speed of rotation, in consequence of this feature, of the rotary engine is the merit upon which superiority has been claimed for it by its advocates from the time of its first introduction, and which has been usually relied upon to compensate what have been supposed to be its defects economically and commercially. These claims are here well sustained, and probably have never been denied. An elaborate calculation of the losses in detail, due to the friction of the parts of the mechanism, has been gone into. This confirms, as closely as need be desired, the results of the test of the rotary, and a comparison with the friction of the reciprocating engine indicates that the latter has a superiority, in this respect, of less than ten per cent of its amount; and this means but about one and a half per cent of the power of the engines compared.

TIN ORE IN DAKOTA.

By William P. Blake, M.E.

Since my former communication upon the discovery of tin ore in the Black Hills of Dakota, other localities have been found. One especially, upon Spring Creek, is worthy of notice. The ore occurs there not only in alluvial deposits in crystalline grains and masses about the size of grains of corn, but in veins of considerable extent and regularity. Samples sent to me show the tin-stone (black tin) disseminated in a gangue or veinstone of white quartz, with a little white mica in small crystals, thus approximating to the composition of typical "greisen." The chief vein is said to be about three feet wide, and to be traceable, but with occasional breaks and interruptions, for a mile or more. It traverses a mica slate.

Samples of supposed tin ore sent to me from Harney Peak consist chiefly of black tourmaline, or schorl. They do not contain tin in any visible quantity, but the black mineral has been mistaken for tin ore by some, and has given rise to local reports of the discovery of enormous deposits of tin-stone.

Development-work has begun on the Etta or Tin Mountain claims, and the ground opens in a very encouraging way, showing large masses of the greisen well charged with cassiterite. A mill has been contracted for and will soon be erected for the purpose of crushing and concentrating this ore. As the concentrations will be very pure and of high grade, it is proposed to ship them to a smelter until arrangements are made for smelting at the locality.

A PATENT DECISION.—The Commissioner of Patents has ruled that distinct and independent inventions, which are differently classified, may not be embraced in one invention. In cases where distinct inventions are dependent upon each other, and mutually contribute toward the production of a single result, the office classification when it obstructs must give way.

MANITOBA & NORTHWEST FARMERS' UNION.—This society has been organized at Brandon. The object is to secure to the province the control of its lands, timber, and minerals; to have the duty on agricultural implements reduced, and to obtain the building of more railroads. One of the speakers at the meeting suggested secession from the Dominion of Canada unless the rights of Manitoba were secured.

FURNACE, MILL, AND FACTORY.

There has just been completed at the F. C. Wells Pump-Works, Chicago, and shipped to the North Chicago Rolling-Mill Company, for its steel-converting works at South Chicago, the largest heavy-pressure pumping-engine ever made in the West. The steam-cylinder of this engine is 32 inches in diameter by 3 feet in stroke, operating on a water-cylinder 11½ inches in diameter. The engine weighs 13½ tons and is 37 feet long over all.

Two Pratt & Whitney machine-guns have just been completed at Pratt & Whitney's works in Hartford, for Gen. U. S. Grant, as presents to the Viceroy of China and the Mikado of Japan. The guns are Pratt & Whitney's improvement over the gun once known as the Gardner gun. The two presentation guns are of the most perfect and elaborate workmanship. Other guns of the same model have a government record of 505 shots a minute, and have been fired at the rate of 700 shots a minute, and 5000 shots in thirteen minutes and twenty-six seconds.

The old Bay furnace machinery, consisting of four boilers, two engines, and a hoist, has been purchased by the Emmet Mining Company for its new furnace at Iron River, Michigan.

A prominent mining engineer informs us that, after severely testing the emery wheel and machine made by the Tanite Company, of Stroudsburg, Pa., for grinding down ore-crushing rolls in place, he has found it to be a great success.

At Croton Falls, N. Y., the Bull's International Iron and Steel Company is putting up a plant to make iron directly from the ore by the Bull process. We understand that the works are to be ready by the 1st of March.

The Boston & Colorado Smelting Company has placed its order with the Lechner Manufacturing Company, Columbus, O., for another chain elevator, and an additional order for roller detachable chain belting, for use in its works at Argo, Colo. This company has also furnished F. L. Carroll & Son, Nona, Texas, and Christie & DeGraff, Detroit, Mich., with detachable chain.

George Point, of Doylestown, O., has leased 250 acres of land in the extreme southwestern portion of Summit County, O. He claims to have discovered a mineral earth or plant which can be used in the place of white lead.

The Lloyd Valve Company, of South Bethlehem, with a capital of $150,000, has been chartered.

The works of the Pittsburg Forge and Iron Company, at Verner Station, have put on another turn, and are now running double in all departments.

The capital stock of the Dunbar Furnace Company has been increased $100,000 and its indebtedness $800,000. The company's two furnaces are located in Fayette County, Pa.

The Iron City Nut Lock Company, Limited, has organized. The capital is $150,000, and the officers are H. W. Oliver, Jr., President; George B. Edwards, Vice-President and Treasurer; John Noble, Secretary; and George B. Edwards, James B. Oliver, H. W. Oliver, Jr., J. H. Noble, T. B. Kerr, and D. B. Oliver Managers.

A party of gentlemen visited the east end of Toronto, Canada, recently for the purpose of selecting a tract of land on which to erect rolling-mills and blast-furnaces. The project is promoted by United States capitalists. No definite step, it is said, will be taken until the government is approached for the purpose of better terms in order to enable the company to compete with British and United States iron-men.

At a meeting of the stockholders of the Scranton Steel Company, held November 27th, it was unanimously agreed to increase the capital of the company from $600,000 to $1,500,000, for the purpose of building a new blast-furnace.

The report of the suspension, on account of a lack of orders, of Miller, Metcalf & Co.'s mill is untrue. The mill is running in every department, and the proprietors report that orders are plentiful.

According to dispatches, the firms of S. B. Lowe and Lowe & Kirk, of Chattanooga, Tenn., made assignments November 26th. The liabilities are about $60,000 and the assets less than $50,000. Lowe & Kirk were in the foundry and machine business, and S. B. Lowe was a manufacturer of metallic paints, and was engaged in a general iron commission business. The Lowe Metallic Paint Company is not affected by the assignment.

Creditors of the Steel Company at Danville, Pa., have proposed to buy the establishment and pay all debts, which amount to $222,000, in one annual and six semi-annual installments. Should this proposition be accepted by the stockholders, the works will run on; if not, a forced sale will cause a suspension. The assets of the company are computed at $234,000.

Center Furnace, at Ashland, Ky., will blow out December 15th, and will not make a blast next year.

A dispatch from Cleveland, O., dated November 26th, says that the new turn taken in the affairs of Brown, Bonnell & Co. creates considerable excitement among iron manufacturers. The scheme of the Brown-Bonnell men is now said to be to get the matter out of court by the payment of the original claim, on which a receiver was appointed; but whether it can be paid or not is a question, as there are other creditors with claims footing up to over a million of dollars. Arguments in support of the intervening bills, put in by the Pittsburg Citizens' National Bank, will be heard before Judge Walker in a few days.

Alan Wood & Co., J. Wood & Brothers, and J. Wood Lukens, iron manufacturers of Consbohocken, Pa., have posted notices around their respective works announcing a general reduction of wages, which will go into effect on Monday, December 3d. The wages of employés receiving $1.50 per day and upward will be cut down 10 per cent; hands who receive $1.40 will be reduced to $1.30; and laborers' wages will be lowered from $1.17 to $1.15 per day. This sweeping reduction applies to all mill hands except the puddlers, who are working under a scale of Pittsburg and Philadelphia prices. The puddlers were "cut" several weeks ago, and it is understood that they will suffer another reduction in a short time. Dullness of the iron trade is given as an excuse for the lowering of wages; and it is understood that the iron-workers will submit to it with a good grace.

For several weeks past, Colebrook Furnace No. 2, at Lebanon, Pa., has been using bituminous coal as a fuel in place of anthracite, and the experiment has given excellent results. The product of the furnace for last week, with all coke and bituminous coal, using Cornwall ore exclusively, was 602 tons. At present, the charge of fuel is 1950 pounds of coke, to 150 pounds of bituminous coal. When anthracite was burned, it was not found possible to use more than 1500 pounds of coke in a charge of 2100 pounds. The use of bituminous coal secures lighter pressure and generally better results. This we believe to be the first furnace east of the Alleghanies to use bituminous coal and coke exclusively.

GENERAL MINING NEWS.

ARIZONA.

The Florence *Enterprise* says that the Pioneer mill, five stamps, started up May 1st, and has produced, up to October 31st, $64,025 in bullion and $9480 in concentrations, making a total of $74,355 for the six months' run. The Howard mill, 10 stamps, started up July 1st, and produced, up to October 31st, $48,672 in bullion as the result of a four months' run. Considering the fact that these companies have had some trouble with their employés and delays caused by the non-arrival of supplies, the showing made is a highly creditable one. Until Mr. W. B. Hellings was given full charge, the output, comparatively speaking, amounted to very little; but under his able and energetic superintendence, order was restored out of chaos and the above splendid showing made. The Howard mill is now shut down for the purpose of changing it to a dry crusher and putting up roasters, the ore now being too base for raw amalgamation. As soon as the necessary change can be made, the mill will be started up again. The Pioneer shipped two bars of bullion this week valued at $2968.

Digitized by Google

CALIFORNIA.

AMADOR COUNTY.

PLYMOUTH CONSOLIDATED.—The secretary reports that the mine is looking well and gradually increasing its product. The output for the first half of November is valued at $47,189.

KERN COUNTY.

SUMNER.—A recent fire has done considerable damage to the property. The latest dispatches from Caliente, where the mine is located, state that the fire is in the upper and 160-foot levels, and that it is impossible to say how far the flames are progressing or to estimate the damage. The works are situated at Kernville, forty miles distant, and cost from $750,000 to $1,000,000. The origin of the fire is unknown. There is no insurance on the property.

MONO COUNTY—BODIE DISTRICT.

Mr. Irwin C. Stump, assignee in insolvency, sold at Bodie, November 19th, the mining ground and all appurtenances and fixtures of the Noonday Mining Company, the North Noonday, and the Red Cloud Consolidated Mining Company, to satisfy judgments amounting in the aggregate to over $550,000, besides costs. The property was sold to the highest bidder, Mr. A. E. Davis.

SIERRA COUNTY.

ALASKA.—The hoisting-works, which were some months ago destroyed by fire, have been rebuilt and started up. The water in the shaft has been lowered seventy feet.

SIERRA BUTTES.—At the mine, grading has been commenced preparatory to building a tramway between tunnels No. 8 and 9. The new mill at No. 9 tunnel is nearly covered.

CANADA.

PROVINCE OF MANITOBA.

A dispatch from Winnipeg to the New York *Tribune* states that a glowing account of newly-discovered mineral wealth in the Rocky Mountains comes from the terminus of the Canadian Pacific Railroad. Persons just returned from those regions declare that the mountains in the vicinity of the Bow and Kicking Horse rivers, as well as many smaller streams, contain gold. Scores of men have spent their time in prospecting, and the numerous rich finds show how their exertions have been rewarded. Leads have been discovered and claims staked out in every direction. Castle Mountain is said to be rich in silver ore. Among other places where promising leads have been found are Johnson's and Baker's creeks, while some which are considered the best yet discovered are situated in the Kicking Horse Pass and are owned by the Tunnel Mountain Mining Company. This company owns several claims carrying both gold and silver. Samples of the ore have been sent to Montreal for assay, and the returns show them to be very rich. The company will open an office at Bow River Forks, and intends to begin operations as soon as the weather will permit in the spring. The gold is chiefly free milling.

NOVA SCOTIA.

COXHEATH COPPER MINING COMPANY.—Thirty-four assays of ore taken from various parts of the mines at separate times, showing from 5·8 per cent to 26·6 per cent copper, have averaged 13·3 per cent. At a depth of 150 feet in the main shaft, the ore next the foot-wall of the vein has contained a considerable showing of silver with a high grade of copper.

ONTARIO.

CALABOGIE.—The first car-load of iron ore from this mine has reached Kingston. The Kingston & Pembroke Railroad now connects with the mine, and a siding has been built for the acommodation of the company.

COLORADO.

CRŒSUS *vs.* COLORADO LAND AND MINERAL COMPANY.—The Denver *News* says that the suit of the Crœsus Mining and Milling Company *against* the Colorado Land and Mineral Company has occupied a good deal of the time of Judge Hallett, in the United States Circuit Court. Each company filed adverse suits against the other for the possession of certain mining property. The matter in immediate controversy in the suit is the adverse claims between the Bernadotte & Maximus and the Nova Scotia Boy No. 2 lodes, in the Ten-Mile District, Summit County. The jury trial resulted in a verdict for the plaintiff for possession. The defendant moved for a new trial. A great many of the leading attorneys in the State are engaged in the case, which opens up some important questions in an old and long-standing suit. Judge Thatcher appeared as senior counsel on one side, and Hon. Thomas M. Patterson on the other.

CLEAR CREEK COUNTY.

HUKILL.—The mine has been leased.

PAY ROCK.—The mill has been shut down for the winter, owing to freezing. The mill, during the past season, has worked to entire satisfaction and with good returns for the company. In the spring, work will be resumed. The lower level of the Pay Rock, which lately was filled with water, has been pumped almost dry, and developments will soon begin.

DOLORES COUNTY.

GRAND VIEW & PHŒNIX.—Work was begun on these mines November 1st. The vein in the last-named mine varies in width from two to four feet, and the character of the ore is lead carbonate. The ore in the Grand View is of a quite different character, and is very peculiar, difficult to sort with any accuracy. Preparations are making to blow in the small furnace, and the run will begin on Phœnix, Grand View, Silver Bell, and Little Maggie ore.

FREMONT COUNTY.

ROCKY MOUNTAIN MINE DEVELOPING COMPANY.—The copper plant of this company is rapidly approaching completion. The plant is new throughout and in all its parts adapted to the economical reduction of copper ores. The company's mine is thoroughly developing, and by the time the smelter is in operation will be capable of maintaining a large daily output.

HINSDALE COUNTY.

CROOKE MINING AND SMELTING COMPANY.—A four-foot vein of galena, rich in gray copper, assays giving from 107 to 170 ounces, has been struck in the third level, at a surface depth of 120 in the Ute mine.

LAKE COUNTY.

BRIAN BORU.—A new strike of fine carbonate ore was recently made. The mineral consists of a dark sand and light-gray hard carbonates. The ore all contains a great deal of lead, and will doubtless also carry some gold and silver.

CUMMINGS & FINN.—The price paid by Messrs. Grant, James & Eddy for these smelting-works, several mill-sites, and a number of mining claims is stated to have been $150,000.

ENTERPRISE.—The Forepaugh shaft of this company, situated just east of the Little Sliver mine, is passing through material presenting a very encouraging appearance. The shaft has a depth of 370 feet. The bottom of the shaft is in iron.

HENRIETT.—Some of the low-grade dump material is concentrated by the aid of hand-jigs with very gratifying results. The jigs are stationed in Stray Horse Gulch, a few hundred feet from the mine, and water forced up by steam is used to wash the ore. The washing is done on a royalty of twenty-five per cent, and proves profitable to both the mine and the parties operating the jigs. The low-grade ore runs about four ounces in silver to the ton and from ten to twelve per cent in lead. The concentrates by assay contain seventeen ounces in silver and fifty-four per cent in lead.

LA PLATA.—Four of the large furnaces at the reduction-works of this company have been blown in. The works had been out of blast since September 15th, at which time they were closed down on account of the inability of the management to secure ore on contracts that would leave a profit on the operation of the works. The suspension of work was also due in a large measure to the necessity of making improvements and alterations, without which it would have been impossible to operate the smelter successfully and profitably.

LITTLE CORINNE.—A lease for eighteen months has been secured by several gentlemen at a reasonable royalty. The lessees propose to put the mine into good working shape.

LUZERNE.—The mine is again taking out some fine sand carbonate ore. The shaft and workings of the mine are evidently not as deep as they should be to admit working to the best advantage, as the ore-bodies are not drained and the mineral comes up wet and mixed with waste. The difficulty, it is stated, will soon be remedied by sinking the shaft deeper. A new shaft has been started about one hundred yards northeast of the Luzerne, which has attained a depth of 120 feet.

ST. LOUIS.—This mine, formerly the Miner Boy and Colorado Prince mines, is hipping about fifteen tons of ore a day. The product of the mine is of good grade, carrying considerable gold in addition to the silver.

OURAY COUNTY.

The Cimarron and Union mines have closed down, as a result of the strike of the Miners' Union. It is expected that the Smuggler will also close down.

MENDOTA.—A strike has been made in the lower level, which is run at a distance of 125 feet from the surface. The ore runs extremely high, averaging 250 ounces in silver. The vein-matter is principally composed of gray copper, brittle silver and ruby. The lessee is taking out about twenty tons of ore a day.

PARK COUNTY.

Brunk's mill, at Montgomery, will run all winter with ten stamps, and will do custom work for the mines in that neighborhood. Among other works, Mr. Brunk expects to run considerable ore for the Crystal Lake and Sovereign companies.

WYANDOTTE.—The new developing tunnel is progressing finely. It will reach the contact about the 1st of February.

SUMMIT COUNTY.

The Leadville *Herald* states that some of the creditors of Mr. Greer, of Kokomo (lessee of the Robinson mine), became uneasy recently and attached Mr. Greer's concentrating mill. The first attachment was made at the instance of Messrs. Ellis & Lowe, the owners of the Colonel Sellers mine in Ten Mile, who have a claim of two thousand dollars. When their action became known, Messrs. Gleason & Lovell, the lessees of the White Quail mine, also attached the mill to secure three thousand dollars still due them on ore shipped to the Greer mill. Mr. Greer is making an effort to extricate himself from the financial embarrassment into which he has been precipitated by the action of his creditors.

CLINTON.—Mr. W. W. Burr, manager of the Clinton mine on Battle Mountain, near Red Cliff, has returned from Philadelphia and reports the sale of this mine to Mr. Whitaker Wright and others.

INGERSOLL.—The owners of this placer claim have begun suit against the Denver, South Park & Pacific Railroad Company for thirty thousand dollars damages. The plaintiffs are the owners of the Ingersoll placer, situated in Little English Gulch, in California Mining District, and said placer contains 156·28 acres. In the placer, there are two lode claims, called the Lincoln and Hurricane.

DAKOTA.

ESMERALDA.—Work has been suspended at this mine and mill. The Black Hills *Pioneer* says that no reason is as yet announced; but it is rumored that the Lancaster Company is to acquire possession by purchase or lease, and that cessation of work will be temporary only.

ETTA.—According to the *Index*, A. J. Simmons contracts with the other owners, for one half of their several interests in the property, to place machinery on it consisting of ten stamps, Blake crusher, concentrators, tramway from mine to Grizzly Gulch, and to open the mine. Work has been begun. With the machinery proposed, it is expected to produce two and a half tons of clean oxide a day, which will be shipped out for smelting until the mine pays for erecting the necessary smelter, which it is thought may be advisable to place in Rapid City.

FATHER DE SMET.—The superintendent's report for the week ended November 15th shows: Ore extracted from first level, 1200 tons; second level, 600 tons; third level, 300 tons. Ore milled, 2100 tons. Golden Gate cross-cut, third level, was advanced two feet; Golden Gate south header, third level, advanced four feet.

MINNESOTA.—The mine has been bonded, but not sold, as reported. Work will be commenced soon.

GEORGIA.

KEYSTONE.—Work has been resumed at this mine, which has been idle for some time.

IDAHO.

ELKHORN.—The expense of operating this property—situated near Ketchum—from December 7th, 1882, to November 7th, 1883, just eleven months, was as follows:

Labor, salaries, board	$24,536.23
Incidentals, taxes, assaying, etc	505.91
Tools, iron, candles, etc	2,480.72
Hauling ore, etc	5,102.18
Timber for mine houses, etc	2,595.29
Incidentals	152.00
Total	$35,373.53
Ore sold	161,841.22
Net profit	$126,467.69

Besides this, 200 tons of ore have been delivered at the smelters, for which the company will receive $90.25 per ton, making about $18,000 to add to the net profits of the eleven months' operations.

HOLYOKE.—This company is working three claims in the Snake River, the Juniper, Omaha, and Bonanza Bar. The prospect for a long continuance of bullion production are very favorable.

MIDA.—The company's grounds, besides carrying fine free gold, contain large quantities of black sand, which is also rich in the precious metal, and the company's methods enable them to save the gold and black sand in bulk, which may be concentrated so that one ton of it will yield from $200 to $800. These concentrators can be used by the smelters in making up their charges, which will increase the value of the bullion produced. During the past season, which has been spent largely in experimenting, the company has washed about 200 yards of sand daily. In the spring, it will start up more extensive machinery, which will enable it to treat 1000 yards of dirt every twenty-four hours.

PHILADELPHIA MINING AND SMELTING COMPANY.—E. G. Mathews, president, and Mr. Rhodes, vice-president of this company, recently inspected the smelting-works before shutting down for the winter. The mildness of the weather has permitted the hauling of ore and the running of two stacks, which turn out an average of 17 tons of bullion a day.

WOOD RIVER.—The Bullion and Ophir mines yield from 20 to 30 tons a day. The recent discharge of some 75 men from the Bullion mine took place because a great deal of dead-work which had to be done is completed.

Digitized by Google

MICHIGAN.

The following table, given by the Marquette *Mining Journal*, exhibits, in gross tons, the total lake shipments of iron ore from upper peninsula ports the present season, up to and including November 21st, together with the amount shipped from the same ports during the corresponding period of last year:

Name of port.	1882.	1883.
Escanaba	1,728,458	1,404,469
Marquette	941,288	692,906
L'Anse	70,543	64,803
St. Ignace	59,157	56,558
Total	2,799,426	2,218,736

Showing a decrease of 580,690 gross tons.

CANAL.—The exploration workings are about midway between Crystal Falls and Republic. A reddish-brown ore, claimed to be Bessemer in quality, has been struck in one test pit. The volume of water is so great that it prevents sinking beyond a certain depth, which is not very great. Nothing but a hand-pump is now used.

DETROIT.—The mine has finished its contract with the Vulcan furnace, at Newberry, and has ceased shipments from the mine for the season. About 10,000 tons were sent out this year. The property is now in first-class shape and can make a much better showing the coming year.

KNOWLTON.—According to the *Iron Agitator*, a party of Ontonagon County citizens has secured control of the old Knowlton copper mine, and is making preparations to operate it. Arrangements for adequate machinery for unwatering the mine are making. The Knowlton lies between the Mass and Caledonia mines, and has been filled with water to the adit level for several years past. Above this point, some work has been done by tributers, and some large masses have been encountered. The tributers have used only mass and barrel work, as there were no facilities for stamping, and it is thought that it is the intention of the new company to erect stamps to treat the copper rock that has thus far been thrown aside. The mine has produced 263 tons 973 pounds of copper, and it is believed by those having the property now in hand that they will make a success of it. The Knowlton, Mass, and Butler veins cut across the southeast corner of the property.

SEDGWICK.—Mr. Henry R. Mather, receiver, advertises that he will sell, December 17th, at public auction, in the city of Marquette, the property of this company—the northeast quarter of southeast quarter and south half of southeast quarter of section twenty-eight; the northeast quarter of northeast quarter of section thirty-three; and one and a half acres of land in southeast corner of southwest quarter of section twenty-eight (being 15 rods north and south by 16 rods east and west), all in township forty-eight, north of range twenty-six, west.

MONTANA.

LEWIS & CLARKE COUNTY.

HELENA MINING AND REDUCTION COMPANY.—The company has about completed its works, and has an 80 and a 150-ton concentrator, and two 20 ton furnaces, and a 20-ton mill. The company will mine at least 250 tons a day. The bulk of this will be concentrated and shipped. This company's property formerly belonged to the old Alta Montana Company.

SILVER BOW COUNTY.

GENEVA.—The lead, located southwest of the Bonanza, on being prospected, shows an average return of 86 ounces silver and $4.90 gold.

SHONBAR.—A rich chute of ore has been opened in the 220-foot level for a length of 200 feet, with splendid results. The new strike is three feet wide, and samples $100. The company is now working fourteen men, has 2000 tons of $40 ore on the dump, and has produced $100,000 in the last fifteen months. It has a complete hoisting and pumping plant.

NEVADA.

A dispatch, dated November 26th, states that the Holmes Mining Company has obtained a judgment of $360,000 against the Northern Belle Mining Company for trespass.

ELKO COUNTY.

NAVAJO.—The mill has been started up and works satisfactorily.

EUREKA COUNTY.

ALEXANDRIA.—The Diligent shaft is down 250 feet, and will be carried to a farther depth of 50 feet, when drifting will be commenced from that point. At present, the work of development is slow, but when spring opens, will be pushed ahead rapidly. Tributers are exploring the old works, and are successful. One set at work on the Sterling tunnel has about twelve tons of rich ore on the dump, which will be sent to the Eureka Consolidated furnaces as soon as it is sacked and ready for shipment.

EUREKA CONSOLIDATED.—Dr. J. C. McKenzie, president of this company, stated, in an interview with a *Sentinel* reporter, that the Selby Works had reduced the cost of refining 6 per cent on the previous cost of refining. The machinery at the Logan shaft is entirely inadequate to do the required work, and part of it will have to be removed. Contracts have been made for coal up to July next, for twenty-five cents per bushel. The dump-pile has not been sold.

EUREKA TUNNEL.—Under date of the 17th ult., Dr. G. H. Thomas, W. Pardy, G. W. Baker, A. Skillman, Gen. P. E. Connor, trustees, and J. Pardy, secretary, have published a circular, of which the following is the substance:

The Eureka Tunnel and Mining Company commenced its work on Prospect Mountain, Eureka, Nevada, January, 1878, since which time the work has been continuous. About December, 1881, the tunnel was into the mountain 2007 feet, having cross-cut 950 feet of ore-bearing limestone, without encountering any large body of ore. Here the primary object of your organization was completed, and the second object, that of mining, commenced. A drift was started on a small showing of ore to the south, resulting in the finding of the present vein or ore channel, which has yielded in gross about $150,000. At the period of this find or strike, the records of the company show its indebtedness May 10th, 1882, $67,986.21, and properly belonging to the cost of tunnel and prospecting drifts therefrom. At this time, a question of title to the ground in which the ore was found arose, resulting in the purchase of a portion of the El Dorado Mining Company's patented claim, at a cost of $21,000. Following this purchase, a call on the stockholders was made of 25 cents per share. On March 6th, 1883, the present board entered upon its duties, when the official report of the secretary showed the indebtedness to be $47,451.60, of which sum $29,443 was in notes issued December, 1881, and a note of May 10th, 1882, for $12,246, a total of $41,689, drawing interest at 18 per cent per annum. To this indebtedness, incurred mostly during the tunnel construction, may be traced the present embarrassment of the company. September 1st, 1883, the report of the secretary shows the company still in debt $47,060.54, to which should be added a sum of accrued interest, not then taken into account. Thus it is shown that the debt of March 6th and that of September 1st, 1883, is approximately the same; during which period the same report shows $52,113 netted to the treasury from the ore product of the six months ended September 1st, 1883, which sum was expended in exploration, production, machinery, and improvements to and surrounding the mine. To the present time, the extraction of ore has been doubly expensive. From the fact that we cut over and down, whereas recent openings from the new shaft will enable us to cut under and up, a difference which miners fully appreciate in cost of ore extraction; that during these explorations we did not find ore in greater quantity, and sufficient to pay the old debt, together with the running expense and cost of improvements, is simply a fact; but our operations were stopped in ore both in the carbonate vein and the chloride vein, first level, while the cross-drifts from the bottom of the new shaft, second level, 700 feet below the surface, show streaks of ore.

The notes of this company having passed into the hands of third parties, payment has become a pressing necessity, and has finally caused the loss of local credit and the present disaster. The property being in the hands of judgment creditors, to rescue it and enable it to resume operations at the mine, we consider it our duty as your trustees to appeal to you for a sufficient sum of money to at once relieve the company from the present and we think also any future embarrassment, and therefore we have made a call for 50 cents per share. It is proper to state to you that a claim for damages is made by one Hartnett for the sum of $23,000, growing out of a transaction between him and General Connor over the purchase of mining ground which he claims the company is liable for, being a deed to this company of the Indus mining claim, and he has brought suit against this company for the above sum based upon such claim. The truth is, that this company never had any transactions with the said Hartnett of any kind or nature, and never purchased said claim from him, and any and all negotiations which were had with him were prior to the organization of said company, and were entered into if at all by Gen. P. E. Connor, and we are advised by our solicitors that the claim is not and can not be a legal charge against this company.

LINCOLN COUNTY.

The Bullionville smelter has closed down after a successful run. Since the smelter started up, it has turned out over 300 car-loads of bullion. This bullion was extracted from a portion of the tailings of Pioche ores, and still it is not half of the precious metals they contain; for, after being run through the concentrating-tables, the residue averages $15 per ton in silver.

STOREY COUNTY—COMSTOCK LODE.

GOULD & CURRY AND BEST & BELCHER.—The winze below the 2500 level passed through a very peculiar formation resembling slag. The rock contained iron, and was exceedingly porous. It has now passed out of the bottom, which is in a formation of block porphyry. A little water is coming in, but not enough to interfere with operations. At the Gould & Curry, the old Bonner shaft is getting into working order. Explorations will be commenced in the old levels which were abandoned several years ago.

NEW JERSEY.

GOVE.—This mine, situated near Drakesville station, one of the most promising iron deposits in Morris County, was to have been sold at public sale at Morristown, November 26th. The ore is of the richest quality, lying upon the celebrated Hurd Mine range, and the workings already done show the existence of a large quantity of ore.

NEW MEXICO.

DOÑA AÑA COUNTY.

SIERRA GRANDE.—Since the opening of shaft No. 11, it has yielded 166 tons of first-class ore, averaging 100 ounces to the ton. The Southwest *Sentinel* says that this ore, which promises to rival the famous Bridal Chamber, lies directly under the road, half-way between the company's office and boarding-house. It cropped to the surface and has been traveled over ever since the first location was made in the camp. The ore in shaft No. 18, which is another new strike and yielding handsomely, proves a connection between the ore-bodies in No. 11 and the strike of last summer, in No. 7. In shaft No. 14, the ore proved eleven feet in thickness, six feet of which are milling, the rest shipping ore, and every indication is, that it will open up larger as work goes ahead. Another new opening has been made on Sierra Grande ground, on what is known as the Railroad claims. This is on the east slope of the second ridge, and is yielding handsomely. This last strike is very encouraging, as it shows a continuation of the ore in the second tier of claims in the Sierra Grande group. Similar bodies of ore had previously been discovered on Bella ground in the same relative position, which yielded largely.

GRANT COUNTY.

GUNSIGHT.—The mine shows a well-defined lead of mineral for its entire length. Parties have begun work on the claim, for an interest.

IVANHOE.—The Kansas City Smelting-Works have contracted for 250 tons of Ivanhoe ore. Shipments have already begun.

MIMBRES.—It is stated that the works have been shut down temporarily. The company intends to make arrangements to resume work on a grand scale.

NORTH CAROLINA.

CID.—Operations were begun the first of this year, and have been continously carried on ever since. The main shaft has attained a depth of one hundred feet, and a tunnel has been opened at a depth of thirty-eight feet, and driven over 100 feet into the south hill. In this tunnel, a five-foot vein of black oxide, containing from forty to sixty per cent of copper, was struck. It is in large quantities. A vein of galena was struck in the shaft. Thousands of tons of copper have been taken out, ranging from carbonates containing three per cent to oxides containing sixty per cent.

CONRAD HILL.—The mine is now worked at a depth of three hundred and seventy-five feet, and yields fifty tons of sulphurets, concentrated to sixteen tons, averaging 7 per cent copper, and milling from eight to ten dollars gold per ton. A twenty-stamp mill running twelve hours a day produces an average of eight hundred dollars a week. The weekly copper product is from twelve hundred to fifteen hundred dollars. About one hundred and twenty-five men are employed. The output of the mine is increasing.

UTAH.

JUAB COUNTY.

EUREKA.—The company recently discharged one hundred miners. One hundred and twenty-five men had been employed, and the monthly output amounted to 1200 tons. Regarding this movement, no explanation is given, but it is believed that it results from the fact that the market is already overstocked with Eureka ore, and that the smelters are getting more of it than they can use to advantage.

MAMMOTH.—The latest reports regarding this company—the difficulties of which we have referred to several times—state that the Englishmen who are interested in the company's property at Tintic have consented to pay the creditors of Bowers & Butler twenty-five cents on the dollar, and, for the purpose of effecting an arrangement on this basis, Mr. Cunningham, one of the original owners of the mine, is circulating among the creditors an agreement for signatures. The Salt Lake *Tribune* says that nearly all the large creditors, representing claims to the amount of $109,000, have already signed the document, and the effort to obtain additional signatures is now making among the small creditors. It is understood that the McIntyre Brothers will stand their proportion of the twenty-five cent settlement, and when they get signatures representing claims to the amount of $125,000, they will, on their own responsibility, buy up the remaining indebtedness at such figures as they can. In view of this proposition, the old assistant-superintendent, A. C. Litchfield, has collected the claims of the miners and other small creditors in his hands, and is holding them in the hope of securing their full payment for the benefit of the interested parties. The claims he represents amount to $25,000, and every effort which has been made to get him into the settlement has thus far failed. It is confidently expected, however, to straighten out the affairs of the company within a short time, and start up work again on the mine.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Nov. 30.

There was but a small business in the mining market this week, and it was quite evident that the two holidays helped to further demoralize the dealings in mining shares. The business was not so generally distributed as was the case last week, but was mostly confined to the low-priced stocks. Of these, Gold Stripe was the most prominent on account of its strength. Decatur, Eastern Oregon, and Sonora were very largely dealt in, but show no important change in price. Of the dividend-paying stocks dealt in, Horn-Silver shows some strength under a small business. Standard was quite strong to-day at the Stock Exchange. Northern Belle suffered a decline of fifty per cent from its price of last week, owing to the Holmes Company obtaining a large judgment against it. The remainder of the market was of but little interest. We give a complete summary below. The total number of shares sold aggregates 106,617, as against 181,738 last week.

The Comstock shares were almost neglected, and of those on the list only the low-priced stocks were dealt in. California sold at 25@23c. Consolidated Virginia was quiet and irregular, selling from 37@32@35c. Sutro Tunnel sold at 15c. under a small business.

The Leadville stocks were quiet at steady prices. Amie sold from 13@12c., with a small business. Chrysolite was quiet and steady, selling from $1.45@ $1.35@$1.40. To-day, 25 shares were sold at $1.30. Dunkin was quiet and steady at 26@25c. Iron Silver was moderately dealt in at steady prices, selling from $2 30@$2 25. Leadville sold at 45c. Little Chief records a small business at irregular prices; it sold from 56@52 53c. Little Pittsburg was steady under a small business, declining from 47@50c. Climax was quiet and irregular at 8@6@7c.

The Bodie stocks were also quiet and steady. Bodie Consolidated was quite strong, under moderate transactions, selling from 50@80@75c. Standard was very quiet and was strong to-day; it sold from $6.25@$7. Bulwer was quiet and steady, selling from 49@46.

The Tuscarora stocks record but a small business at steady prices. Belle Isle sold at 33c. Navajo was dealt in to the extent of 100 shares at $3.75. Independence sold from 20@18c. Elko Consolidated was very quiet at steady prices, selling from 17@18c.

In the miscellaneous list, Alice was quiet and steady, selling from $2.40@$2.50. Eureka Consolidated was weak under a small business, selling from $3.50@ $3.25. Gold Stripe showed some strength and was very active; it sold from 5@10c. Green Mountain was strong, under a small business, selling from $1.30@ $1.35. Homestake was quiet and a little stronger; it sold from $10@10.50. Horn-Silver was moderately dealt in at strong prices, selling from $6.13@$6.50. Northern Belle was quiet and weak, selling from $2.95@$2. The sharp decline in this stock is attributed to the fact that the courts have decided against the company in a suit brought by the Holmes Mining Company for $360,000, the facts of which we have already published. Robinson Consolidated was a little weak, under a small business, selling from 36@32@34c. Sierra Grande was quiet and steady at 90c. Castle Creek sold to the extent of 700 shares at $1.

Barcelona was moderately dealt in at steady prices, selling from 26@28@27c. Bradshaw was quiet and steady at 20@17c. Caledonia was quiet and steady, selling from 14@15c., assessment unpaid. Central Arizona sold at 23c. under a small business. Decatur was very active at steady prices, selling from 6@4c. Eastern Oregon was also very active and was steady; it sold from 47@45c. Harlem was strong, under a moderate business, selling from $1 @$1.10. Sonora Consolidated was very active to-day at steady prices; it sold from 26@24@25c. North Mexican sold on Saturday last to the extent of 1200 shares at 55@50c.

We print elsewhere the substance of a statement by the trustees of the Eureka Tunnel and Mining Company.

MEETINGS.

The Bremen Silver Mining Company, office of Lester W. Clark, No 16 Exchange Place, New York City. A special meeting of stockholders, December 8th, at two o'clock P.M., for the purpose of considering and voting on the question of selling, assigning, transferring, and conveying to Martin W. Brennan, absolutely the owner of not less than one third in amount of all the stock of said company, for the nominal consideration of one dollar, all the estate and property, real, personal, and mixed, of said company, and of dissolving said company.

The New Central Coal Company, Nos. 6 and 6½ Trinity Building, New York City. Annual meeting of stockholders and election of directors, December 11th, from twelve M. to two P.M.

The Silver Link Mining Company, No. 1323 Broadway, New York City. Meeting of stockholders for the purpose of increasing the capital stock from $200,000 to $250,000, December 20th, at twelve o'clock M.

DIVIDENDS.

The Charleston (South Carolina) Mining and Manufacturing Company announces a quarterly dividend of three dollars and fifty cents per share, payable December 1st.

The Lehigh Coal and Navigation Company has declared a semi-annual dividend of three per cent, clear of taxes.

The Morning Star Consolidated Mining Company, of Colorado, has declared a dividend (No. 19) of twenty-five cents a share, amounting to $25,000, payable November 22d.

The Spring Mountain Coal Company has declared a semi-annual dividend of three and a half per cent, payable on and after December 10th.

PIPE LINE CERTIFICATES.

There was a marked falling off in the business done this week in oil certificates, and with the single exception of Wednesday the market was dull and almost featureless. On that day, there was considerable activity displayed, and the market broke and closed weak. To-day's fluctuations have been of a limited character, and although at one time strong, the market broke in the afternoon and closed weak.

It is rumored in the oil-fields that the report of the development-work for November will be "bearish." There has been good clear weather during the month, and this has been favorable to the erection of rigs and the drilling of wells. Besides this, the high prices that have ruled lately have naturally stimulated producers to increase their output.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Nov. 24	$1.18¾	$1.18⅞	$1.17⅝	$1.17¾	4,023,000
26					
27	1.18¾	1.19	1.17⅝	1.17⅝	5,502,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, November 29, 1883.

Owing to the occurrence of two holidays the past week, the market for mining stocks has been extremely dull, and without any feature whatever. Calumet & Hecla sold at $238, the same as last week. Franklin, on sale of 20 shares, advanced to $12. The reports from the mine are very favorable, and it would not surprise us much to see higher prices for this stock at an early day. Quincy continues to be dealt in only in a small way at $52@$51¼. Huron sold at $1— a decline of $⅝ since last sale, September 12th. Nothing doing in the rest of the copper stocks.

In silver stocks, Bonanza sold at $1½. Catalpa advanced from 35@45c., and at the Mining Board sales were made at 48@50c. Crescent sold at 20c., the same as before. Sullivan, 88@92½c. Bowman Silver, steady at 16@19c., but with less activity than last week, although the reports from the mine are of a favorable character. Massachusetts & New Mexico in good demand at 3c. bid. Dunkin, steady at 26@28c. Sullivan sold at 90@93c., and continues to be in active request.

3 P.M.—The afternoon Boards were extremely dull, and without any material change in prices.

BULLION MARKET.

NEW YORK, Friday Evening, Nov. 30.

26	50⅛	110	29	*	Holiday.
27	50⅛	110	30	50⅛	110

* 50⅛@50⅝.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended November 30th, as compiled from various sources, amounted to $214,000, as against $161,000 reported for the previous week. The receipts from January 1st, 1883, to date are $10,530,443.

Exports and Imports of Gold and Silver at New York.

Since January 1st, 1883	13,366,218
Corresponding period last year	45,037,282

Imports.

Week ended November 24th	$558,668
Corresponding week last year	323,534
Since January 1st, 1883	19,459,089
Corresponding period last year	5,809,861

METALS.

NEW YORK, Friday Evening, Nov. 30.

Copper.—Nothing has happened to change the quiet tone of the market, and while quotations are nominally 14⅞@15c., it would be difficult, probably, to get much Lake at the lower price. Other brands are nominally 14⅛@14⅝c., according to quality, with little offering. Undoubtedly the market here is statistically in good shape.

London cables Chili Bars slightly better, the latest figure being £59 10s., with Best Selected quoted last, £66.

Tin.—The week has been a quiet one, the market closing with Straits spot at 19@19½c. for large lines, and Australian 19⅜@19½c. At the Amsterdam auction yesterday, Banca went off at 53½ guilders and Billiton at 52⅝ guilders. London cables to-day, £87 5s.

Lead.—Buyers still maintain their attitude of indifference, and in spite of the fact that lead is undoubtedly low, we see very little cause likely to induce them to take hold. It remains to be seen what producers will do. There seems to be some wild talk in Colorado of "syndicates" to buy the surplus metal and carry values to preposterous figures. We have little faith in such statements when they assume an extravagant form. The gathering of the stock in a few strong hands acting in concert would of course do good, if it were a question of tiding over a momentary panic or convincing consumers that bottom had been reached. We do not believe that such a course would do the

*Non-assessable. † The Deadwood has previously paid $275,000 in eleven dividends, and the Terra $75,000. ‡ This company, as the Western, up to December 10th, 1881, paid $1,475,000. Quotations of these stocks will be found in S. F., San Francisco; B., Boston; and P., Philadelphia, tables. E are British companies. ‖ Total number of shares, 500,000; 50,000 shares have never been issued, and are still held by the company. Dividend shares sold, 40,287. ** Non-assessable for 3 years.

metal any good in the long run. Either production must be curtailed by agreement or by the irresistible logic of unprofitable prices, or consumption must come forward to relieve the market. The latter is not likely to take place for the next six weeks, while voluntary reduction of output when there are so many conflicting interests is out of the question with a stock of many months of ore at the smelters, and, as yet, no wide-

G. Gold. S. Silver. L. Lead. C. Copper. * Non-assessable. † Stocks quoted on S. F. San Francisco; B., Boston; P., Philadelphia. Non-Dividend shares sold, 66,330. Total shares sold at all the exchanges, 106,617

spread decline of the output of the mines. With the freight question on base bullion and refined lead as yet unsettled, the time for speculative purchase has not yet come.

During the week, about 600 tons of Common lead have been sold for January and February delivery at 3·65c., while for spot lead 3·70c. is asked, with nothing doing.

Messrs. John Wahl & Co., of St. Louis, telegraph as follows to-day:

Our market is quiet and dull, with prices unchanged. We quote Refined 3·50c., and Common 3·44@3·50c.

Messrs. Everett & Post, of Chicago, telegraph:

Our market has declined slowly since our last report, the demand being only moderate. There is very little doing, because buyers refuse to take at the price asked, and sellers decline to take less. We quote nominally 3·40c.

Digitized by Google

The Leadville *Herald* prints the following: The effect that the low price in lead is having on many mines in this district is illustrated in the following actual returns received for ore-shipments:

Four months ago, a mine shipped ore containing six ounces of silver, three tenths of an ounce in gold, and twenty-eight per cent in lead. For the various metals in the ore it received respectively, $5.95 for the silver, $5.40 for the gold, and 40 cents a unit for the lead, or $11.20; making a total of $22.55. From this amount $8.50 was paid for treatment, and $7 was deducted for the cost of mining and cartage, aggregating $15.50, which, deducted from the original value of the ore—$22.55—left a margin to the miner of $7.05.

At present, the mine is receiving the same amount for the silver and gold contained in the ore, but only 20 cents a unit for the lead, or just one half of former prices, being $5.60, instead of $11.20. This leaves the total receipts per ton reduced to $16.95. Where heretofore the ore was treated at $8.50 per ton, $9.50 is now charged, to which add the $7 for expenses of mining and cartage, and the mine-owner has a profit left of only 45 cents per ton. It is needless to add that, until a change for the better is experienced, such mines will not ship any ore.

Spelter.—There is nothing new to report. We quote Common Domestic unchanged, at 4⅝@4¼c.

Antimony.—The London market has risen, in consequence, it is said, of a falling off in the ore supply. Here, the advance realized has been maintained, with considerable business doing. We quote: Hallett's, 10¼c. and Cookson's, 11¼c., with futures ⅛c. higher.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Nov. 30.

American Pig.—There have been some slight indications of a better feeling; and notably in foundry irons, there is a tendency to greater firmness which has not yet, however, developed into any thing that will warrant even the slightest stiffening in price. It is not believed that for the near future any notable change in the situation can be looked forward to. Gray Forge is in a relatively poorer condition, buyers holding off persistently. We quote $20@$22.50 for No. 1; $18.50@$19.50 for No. 2; and $17@$19 for Gray Forge, all at tide-water. Bessemer Pig is dull and unchanged, while Spiegel is weaker at $30@$30.50 for 20 per cent metal.

At the Exchange, the following transactions were recorded: Wednesday, 300 tons No. 1, March, $20.25 and 100 tons No. 1, April, $20.50.

Scotch Pig.—There has been a slight increase in the number of inquiries, and the sales are in the aggregate larger.

We quote ex ship and to arrive: Coltness, $23; Langloan, $23@$23.25; Summerlee, $22.50@$23; Eglinton, $20@$21; Glengarnock, $21.75@$22; Dalmellington, $20@$21.

At the Exchange, the following lower cable quotations were received to-day: Coltness, 54s. 6d.; Langloan, 54s.; Summerlee, 53s.; Gartsherrie, 51s. 9d.; Glengarnock, at Ardrossan, 52s. 6d.; and Eglinton, at Ardrossan, 47s. 6d. Warrants at the Exchange to-day were 44s. 2d.

Rails.—The fact has become known here within the past few days that the price taken for the 25,000 ton and other lots of rail, deliverable at Chicago, was really $35, not $36 as reported. One lot of 25,000 was taken by a Pennsylvania mill, and the price is therefore equivalent to $32.25 at mill. It is stated to have been the result of a fight between two Pennsylvania mills, endeavoring to gain a footing in Chicago, and the Chicago companies. There has been little business done this week. Quotations remain unchanged at $35 at mill.

Old Rails.—We quote $22.50@$23.

Philadelphia. November 29.

All things considered, the iron trade is in a little better shape than last week, owing mainly to the fact that a dozen or two large buyers have purchased pig-iron for the next quarter's delivery. If the offers made are accepted, a number of heavy transactions will be closed next week. Some buyers have assigned as a reason for their movement just at this time, that January generally shows a hardening tendency in prices, owing to the fact that so many consumers hold off until the opening of the year, and then rush into market for supplies. A few makers and holders of good brands have shown a willingness to dispose of a slight accumulation of stocks, and the statement is made that sales of between 15,000 and 20,000 tons have been quietly made, covering all kinds of iron, from inferior foundry up to best, and from inferior forge up to two or three special brands. In fact, some makers of special brands claim to be well sold up, and the same favorable report comes from some makers of standard brands. The talk in this direction, if adhered to, will have a good effect upon some buyers who are prowling around the market, waiting for still lower prices, or for the bottom to fall out of the market. Although a slight increase is shown over last month's production, yet the fact that demand is largely withheld shows some of the shrewd buyers that, should the legitimate requirements be presented, prices, especially for the standard brands, would harden at once, and hence it is that they have bought with more freedom. The policy of carrying larger stocks is admitted to be the wise one, and a good many more sales have been made, more for this reason than any other. Gray forge iron of standard make is in fair demand, and the example of two or three large buyers will be followed by others next week, resulting probably in a slight improvement in these brands. Inferior brands are abundant at $17 at furnace. No. 1 Foundry ranges from $20.50@$21.50, with specials at $22@$22.50; No. 2, $19@$20.

Foreign Irons.—A little Scotch iron has been selling this week, but buyers seem indifferent as to future requirements. Spiegeleisen is nominally $30.50 for 20 per cent. There are a few bids in at $29.50, but not much anxiety at this. Bessemer is nominal at $20.50, but buyers are not anxious to place large orders at the present or prospective price of steel rails. Foreign iron, as a whole, is without interest at present writing, and there are no probabilities of any large sales being effected.

Muck Bars.—Sellers are asking $33.50@$34, and sales of between 3000 and 5000 tons could be made at once if $33.25 would be taken.

Blooms.—Small lots are moving as usual at $55@$56 for Charcoal and $47@$48 for Anthracite.

Merchant Bar.—The merchant bar trade is in a very unsettled condition, and it is difficult to state actual prices, although the range is from 1·80@2·10c. Perhaps more iron has sold below 2 cents than above it, and the fact that several mills purpose shutting down at an early day indicates that the demand is far from encouraging. Besides this, reductions in wages have been announced and will take place at once. No objection will be made to this. Common labor is also reduced, and every effort will be made to tide over the dull trade that must be met between this and February 15th. Some manufacturers claim that, after the first of the year, a great deal of demand that is now waiting will be presented and improve prices.

Nails.—The movement in nails continues irregular, and buyers can not be induced to purchase except for actual requirements. Small lots are held at $2.85, and large lots are selling at from 10c. to 15c. less.

Plate and Tank Iron.—Plate iron is without any particular activity this week. Mills are fairly supplied with orders up to the end of the year, but after that there will be sharp competition. Tank iron sells in small lots at 2·50c.; Boat Plate, 2·35@2·40c. A few small lots of plate iron have been ordered this week for January delivery. Boiler-shops are working out old contracts, and are looking confidently for some large orders which will have to be filled soon after the opening of the year.

Structural Iron.—Orders from bridge-works this week show a fair degree of activity, with prospects that a large amount of work will be presented at an early day, and there are large inquiries to hand this week; but the business to which they refer will not be placed until the early part of next year. Quotations are unchanged.

Sheet Iron.—All mills are slacking up, and large orders are solicited at greater concessions than heretofore extended.

Wrought Pipes and Tubes.—There is no change in quotations, and demand is dull.

Steel Rails.—There are rumors of large transactions having taken place in Western mills at $34@$35, but it is thought that no further cutting below $35 will take place. It is said that one or two mills besides the ones already reported will close down. From 8000 to 10,000 tons, in small lots, were ordered here during the week at $36@37.

Old Rails.—Brokers here are moving around lively, looking up American stocks, and the demand is active; but buyers have not had their wants provided for, owing to the difficulty of getting enough material at their own prices. Two sales have been made at $23.25 for Tees and $25 for Double-Heads, but most of the orders in hand are at lower prices.

Pittsburg. November 28.

A fair demand has been kept up all through the week for standard brands of Gray Forge iron, for which, in most cases, $18 was paid. Inferior brands are in less active demand at $17.50; Coke Iron, Foundry, $19@$20; Bessemer, in 50 to 100-ton lots, $21; offers at $20@$20.50, cash. Muck Bars are quiet at $32. The merchant iron trade continues very unsatisfactory, and a further closing down of mills takes place this week, and it is given out that four or five other mills will close down next week; but this will depend upon the course of business for the next few days. Consumers are holding off as much as possible, and will not place large orders until the close of the year. Prices are 1·75@1·90c. More iron has been sent East, and sold at the latter figure. Stocks, however, are very light in first and second hands, and this will have a favorable effect should demand improve. But it is not likely that any great improvement can take place very soon, owing to the heavy capacity that has been laid off. Nails are weak and fluctuating at $2.50@$2.60. The complications in the affairs of Brown, Bonnell & Co., of Youngstown, stand in the way of a settlement. Reports from Wheeling, Youngstown, Sharon, and some of the outlying towns between Pittsburg and those points, show a heavy falling off in output and scarcity of orders for merchant iron. Steel Rails are held here at $35.50@$36 for winter delivery. Some large requirements are held back until there is a further reduction. Small railroad material is active. A further restriction in the production of merchant steel has taken place. Prices are irregular. Crop-Ends, $23.50 for American. A fair movement is in progress in Wrought Scrap at $22@$22.25 for No. 1. Car-Axles, $30@32; Car-Wheels, $19.

COAL TRADE REVIEW.

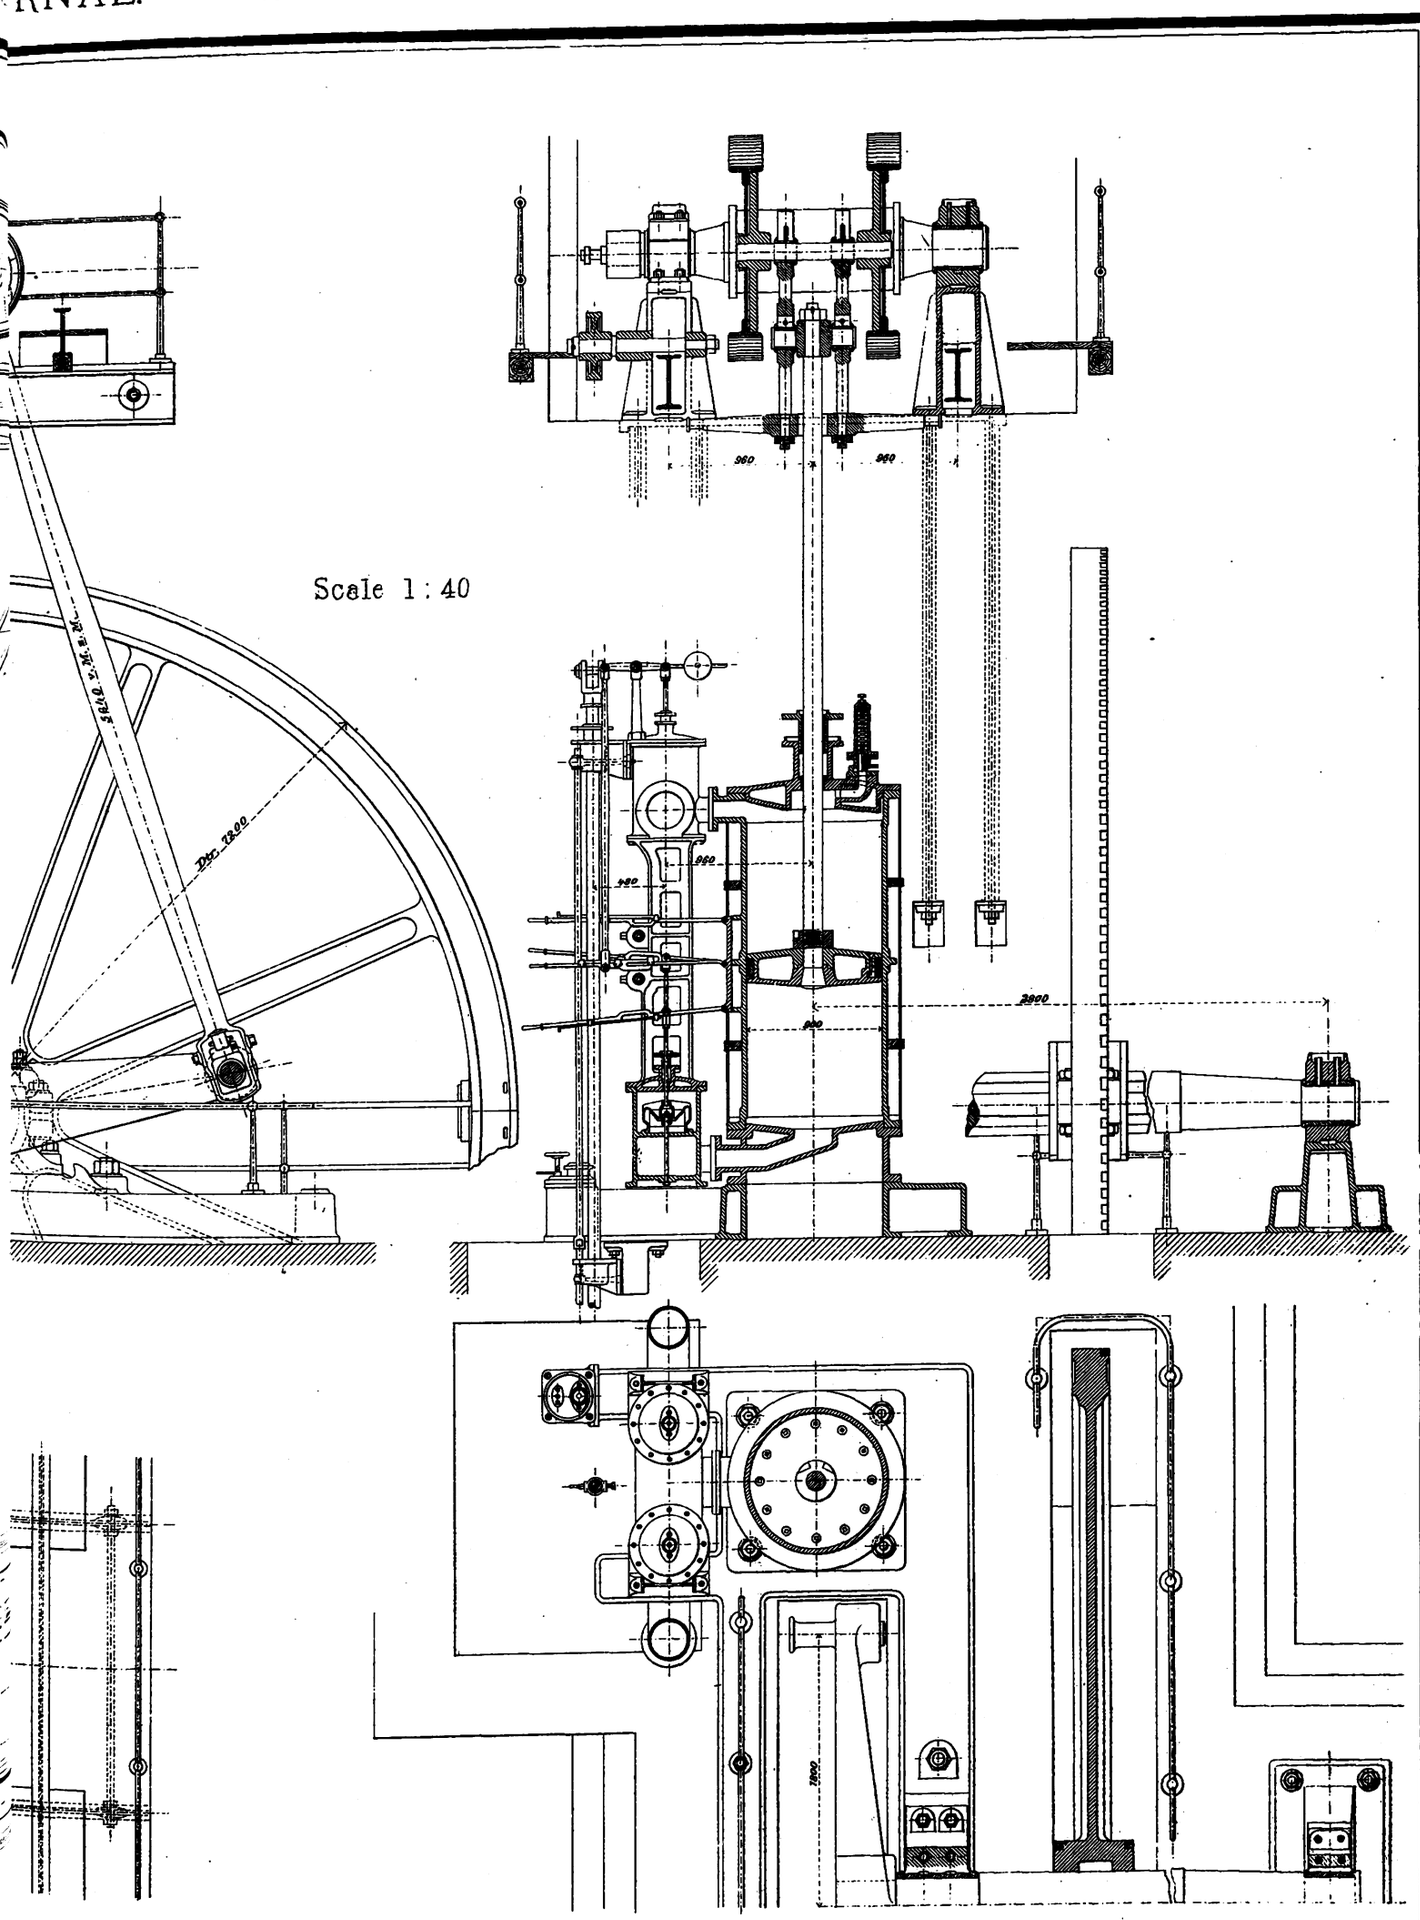
NEW YORK, Friday Evening, Nov. 30.

On Tuesday, and again to-day, there were numerous conferences among the managers of the coal companies, the usual course of one or two going about laboring with their fellow magnates having been adopted. As the matter now stands, the majority have signified their willingness to do whatever the state of the trade requires. All apparently agree that there must be curtailment, but there are two of the presidents who insist that their way is the best to do it. One demands that there shall be three days of work every week, chiefly because it suits his company best, but ostensibly because he has no stock of engine coal, because there is danger of disaffection among the men, etc. The other wants a cessation of mining for two weeks in December, January, and February, to keep the supply within the capacity of a restricted market. We believe that the latter plan is the only one which can effectually keep our market from falling off worse than it has done already. Stove coal is selling as low as $4.05@$4.15, and there is enough in sight to keep buyers supplied for some time to come, unless the weather takes a more favorable turn.

Bituminous.

There are no new features. The vessel supply at shipping points is getting better than it has been.

Horsford's Acid Phosphate.



Beware of Imitations.

Imitations and counterfeits have again appeared. Be sure that the word "HORSFORD'S" is on the wrapper. None are genuine without it.

UNDER the energetic and efficient management of Dr. A. VON GRODDECK, the Clausthal School of Mines has evidently kept abreast of the progress of the times. A well-illustrated pamphlet which has just reached us gives an interesting sketch of its history, of the great mines and works in its vicinity, which afford such exceptional facilities for the study of practical mining and metallurgy, and of the elaborate system of instruction it offers to students.

SOME time since, the world was informed, through the medium of an associated press dispatch, that a new process sounding the oft-repeated death-knell of the puddling process had been tried at the Edgar Thomson Steel-Works with much success, a steel very low in carbon being produced. We understand that it is a slight modification of the Bessemer process, consisting in running in the spiegel before the usual time and blowing till a steel very low in carbon is produced. We are informed that the product is excellent, and is likely to overcome the troubles hitherto experienced with Bessemer metal for structural and machinery purposes.

THE Second Geological Survey of Pennsylvania, of which Mr. CHARLES A. ASHBURNER is geologist in charge, is about to issue four additional sheets of the survey of the anthracite coal-fields. Three of these sheets are a reproduction, with certain additions, of the topographical map constructed for the Lehigh Valley Coal Company, by STEPHEN and JOSEPH S. HARRIS and A. J. WOMELSDORF, from 1868 to 1875, and supplemented by maps of special areas constructed by LEWIS A. and S. RILEY, and the Second Geological Survey. This map gives the topography in 10-foot contour lines of that portion of the Western Middle coal-field between Quakake Junction and Mount Carmel. To the original map have been added north and south and east and west lines, 2000 feet apart, referred to the true meridian, and the approximate outcrop of the lowest, the Lykens Valley coal-bed, and a number of other features. The fourth sheet gives the details of the Mount Carmel, Centralia Coal Ridge or Montana, Germantown, and Mahonoy basins, on the general plan repeatedly referred to in our columns.

Here, we may call attention to the fact that the Survey has recently made a modification in its plan of selling these maps which will commend itself very favorably to intending purchasers. Hitherto, the Survey has not offered them for sale before an entire atlas was completed. Now two hundred copies of each sheet, of an unfinished atlas, will be sold singly, as soon as printed, and those who have immediate use for them can therefore procure them by addressing Mr. WILLIAM A. INGHAM Secretary, 907 Walnut street, Philadelphia. The topographical sheets referred to above will, we understand, be sold at a price of eleven cents each.

THE following figures, from the report of the Bureau of Statistics for the year ended June 30th, 1883, show who during that time had been our principal customers for copper, in the form of pig and ore, the former, we presume, including matte, while the latter embraced probably black copper as well as the refined metal:

	Ore.		Pig, Bar, and Sheet.	
	Cwts.	Value.	Pounds.	Value.
Belgium	10,080	$3,550	.....	.....
Central American States	.....	.....	6,656	$1,128
Chili	.....	.....	2,000	370
Danish West Indies	.....	.....	1,634	497
France	.....	.....	6,101,301	989,626
Germany	6,454	65,449	234,270	37,259
Great Britain	96,045	871,122	1,282,115	188,172
Canada	.....	.....	339,042	33,341
British West Indies	.....	.....	806	153
Hong Kong	.....	.....	2,753	405
Hawaiian Islands	.....	.....	3,579	757
Mexico	.....	.....	2,685	805
Netherlands	344	3,650	220,183	35,525
Cuba	.....	.....	7,890	20,089
Colombia	.....	.....	6,257	1,364
Venezuela	.....	.....	10,192	2,456
Total	112,923	$943,771	8,221,363	$1,293,947

France, therefore, takes by far the bulk of the finished product, while Great Britain calls for the largest quantity of the raw material. It is, of course, impossible to give any estimate of the quantity of copper contained in the ore and matte sent away; but even making allowances for the fact that there is usually silver in both, a comparison of the values indicates that the 113,000 cwts. of "ore" contain at least as much as 8,000,000 pounds of copper.

THE opening of Congress has unfortunately been marked with strong indications of a revival of the discussion of the tariff that has caused some uneasiness. The business community has for some time past, in looking into the future, regarded the fact that next year is again to see a struggle for the presidency as one of the leading grounds for setting aside hopes of a marked improvement. The possibility that our tariff policy is to be made one of the leading issues in the struggles for the ascendency of one or the other party is not reassuring. The election of Mr. CARLISLE as Speaker of the House of Representatives, as the leader of a section of his party pronouncedly in favor of a further reduction in the tariff, is a new phase, aggravating in its character. It is not likely that any sweeping or general changes will be made during the present session of Congress, because it is too early to appreciate the effect of the recent reductions in the duties upon the revenue. We believe that public opinion will demand that a pause be made to note whether there was a gain, and how much it amounted to. Thus far, the main object of the revision of the tariff, a reduction of the income of the government, has been disappointing. It was estimated that the falling off in revenue would be about $55,000,000. In reality, it has been only $20,000,000, in spite of the fact that business has been poor. The President does not appear inclined to sanction any radical changes, and yet it is likely that repeated and well-directed efforts will be made to make political capital out of measures looking toward a "tariff reform." The policy followed will, we believe, be similar to that adopted previous to the general onslaught on the tariff, that of selecting individual industries for an attack. It is not

Digitized by Google

likely that much will be accomplished; but the agitation and suspense will not be conducive to an encouragement of buyers whose hand-to-mouth tactics have wrought so much harm during the past year.

THE suggestion has been made that those interested in mining and allied industries take some united action to secure a continuation of the work so worthily begun under the auspices of the United States Geological Survey, of officially collecting the statistics of the production of coal, oil, minerals, and the base metals. A number of individuals and newspapers have, with commendable zeal and enterprise, devoted much earnest work to carrying out what they know to be a matter of the highest importance to their respective industries or constituents. And yet few of them will fail to acknowledge that they have not at their command the means, the time, and the *prestige* which the work really demands. We can speak frankly on this subject because we have ourselves had a good deal of experience. We have met with the most graceful and hearty co-operation on the part of the majority of those to whom we have applied, only to find that misrepresentations, purposely made, endangered, unless carefully guarded against, our whole work. We have reached the conclusion that individuals may reach a point where they can vouch for their figures as close approximations, but they can not, unless they have exceptional facilities, attain absolute accuracy. When gathered under the auspices of such a department as the Geological Survey, data are obtainable which are withheld from any body else, because they go into the hands of entirely disinterested parties who ought to command and do command absolute confidence.

Our own personal acquaintance with the gentleman who conducted the recent work of the Survey gives us the right to state that we believe that its progress would be as little hampered by red tape as is possible in a government office. A suggestion has been made, in which we heartily concur, that a petition be circulated in which a special appeal be made to Congress, through the intermediacy of the Geological Survey, to provide ample means for this work. We have no doubt that such an influential body as the American Institute of Mining Engineers would give the movement its hearty indorsement, if its co-operation could be secured in time. Unfortunately, its next meeting will not be held until February next, so that action from that quarter can not be looked forward to, to be available in time.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. Our Imports of Steel from Belgium.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: In your interesting Summary of Statistics of Imports of Iron and Steel, you observe, with reference to the large quantities of steel imported from Belgium, that you "believe very few are aware that Belgium is so large an exporter of steel to this country." As a matter of fact, comparatively little, probably not more than twenty per cent of the steel which figures as imported from Belgium, is really made in that country. The large Westphalian and Rhenish steel-works (Germany) can ship at about equal cost to Rotterdam (Netherlands) and Antwerp (Belgium), and to either port more cheaply than they can to Hamburg or other German ports. Consequently, the bulk of the German exports of steel figures as from Holland and Belgium. Yours truly, P. B.

NEW YORK, Dec. 5.

The Dora Coal-Field, Virginia.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: In the November number of *The Virginias* is contained a review of the report on the *Mineral Resources of the United States*, recently published by the United States Geological Survey, which contains the following: "In Mr. Charles A. Ashburner's report on anthracite coal, page 32, is this statement concerning the *Dora coal-field:* Of one of the reported anthracite localities in Virginia, that in Augusta County, recent tests with the diamond drill would seem to prove the presence of anthracite," etc. In explanation of the above, I would like to state that, by referring to the report reviewed, on page 24 will be found a foot-note as follows: "Mr. Ashburner's contribution and statistics end here." I only stand responsible for a *portion* of the statistics relating to the anthracite region in Pennsylvania (pages 7 to 24 inclusive). I desire to make this explanation public from the fact that I do not wish to be held accountable for *questionable data* relating to a coal-field of a very uncertain character, and which I have never examined. Yours respectfully,

PHILADELPHIA, PA., Dec. 5. CHARLES A. ASHBURNER,
Geologist in Charge Penn. Anthracite Survey.

DELAWARE & HUDSON CANAL.—The last loaded boat on the Delaware & Hudson Canal started from Honesdale, Pa., November 29th, for Roundout. The total shipments by the canal this season have been 1 114,875 tons.

THE CABLE GRIP PATENT INFRINGED.—A dispatch from San Francisco says that the Cable Railroad Company, owner of the street-car patent cable grip, the same that is used in Chicago, has begun a suit against the Market Street Cable road, owned by Stanford & Crocker, for $100,000 damages for infringement on the cable grip patents.

THE VERMONT METHOD OF HEAP-ROASTING COPPER ORES.

Written for the Engineering and Mining Journa

For heap-roasting copper-bearing pyrites, the conditions of success are few and simple: Arrangement of wood under the heap, proper sizing of the ore, volume of the heap, firing, and covering. But all these must be properly performed. It is scarcely necessary to say that the bed upon which the ore is roasted must be well drained. It is constructed precisely like the traffic way of a city street, seventy feet wide, and the center six inches higher than the gutter on each side. The roast-heaps are laid across the bed, and are best twenty-four feet wide and fifty feet long. For convenience in covering and stripping them, they should be placed about eight feet apart, or even a little more. Each heap will then occupy about thirty-two feet of the length of the bed. The wood used should be four feet long, sound, and partly seasoned. It may be three inches diameter, or as heavy as one man can well handle. Ordinary split wood is best, of course. Brush, rotten timbers, or any thing else that will burn may be used; but a good roast will certainly not be obtained with any such material.

The plan of the heap should be laid off in the form of a parallelogram, 24 feet wide and 50 feet long, and wood piled 9 inches deep all over the plan. The work is begun by laying sticks of wood, about 3 inches diameter, end to end, across both ends of the plan and about 6 inches within the boundary. Vertically across these, the best wood on hand is piled closely, and to the required depth, bringing the outer ends evenly to the boundary. The ends of the piles will be part of the sides of the heap. Split sticks are used at those ends, and they are so piled that they will form a nearly vertical wall nine inches high; otherwise, ore will roll off in building the heap. The small sticks first laid will keep the outer ends of the wood away from the ground, and thus facilitate firing. Next, small wood is laid, end to end, along so much of each side of the plan as is not already covered, and about six inches within the boundary. Vertically across these, wood is piled to the required depth, bringing the outer ends evenly to the boundary. There is now a border four feet wide all around the plan. The space within this is yet to be filled. Work is begun at one end of it and wood piled in, laying all the sticks parallel with each other and with the long axis of the plan. Here the largest and smallest sticks are used, the best wood being in the border mentioned. A close inspection must now show that there are no spaces through which ore may fall to the ground. If the work has been well done, the wood will be closely piled nine inches deep all over the plan, and will reach evenly out to the boundary all around it, and these form a sort of vertical wall of that hight; and further, where the ends of the sticks reach the boundary, they will be raised away from the ground by the small sticks first placed for that purpose. The wood is now properly arranged for firing.

Ore in 1½-inch cubes is a good size for roasting. But unfortunately, after passing through the rock-breaker, it is all sizes, from two-inch cubes down to dust. It is first passed over an iron screen inclined thirty degrees below the horizon, and with holes 1⅛ inches in diameter. What passes through this is allowed to fall upon another screen with ¼-inch meshes. What passes over this screen is called "ragging;" what goes through, "fines."

The heap is begun by putting a layer of ore three feet deep all over the wood, as already arranged, and pushed out to the boundary until the slopes are as steep as can be made to stand without ore falling off the wood. Pains should be taken to make all slopes plane surfaces. Another layer two feet deep, and yet another two feet deep, are now put on, taking pains to keep the slopes as steep as they will stand and to have them plane surfaces. The ore is piled seven feet deep above the wood. Upon the top of this one foot deep of ragging is put, and the heap is complete. After the fines have been arranged in piles all around the heap, and about three feet distant from it, all is ready for firing. To do this, a fire is built at once up against the wood all across both ends of the heap. In an hour, the wood under it will take fire, and in another hour the ore will begin to ignite. It must henceforth have every attention. As soon as the ore has ignited, from the ground one foot upward, fines by the shovelful are dashed evenly upon the ignited part until it is covered half an inch deep. The ignition will proceed upward, and from both ends inward toward the center of the heap. As it does so, the scattering of fines upon it is continued, so that only the edge of the ignited ore may be visible. The heap for a week or more will grow hotter and hotter, and yet no part of it must be allowed to fuse. The covering of fines must be kept nearly cool enough to allow of one's hand being held upon it, and this can be done only by increasing the thickness of the covering. As it warms up to the proper temperature, more fines are scattered on with a shovel, and with the back of it they are patted down to keep them in position. When the fire reaches the top of the heap and begins to move along it, fines are thrown up there, and the workman climbs up an angle to the top and scatters on the covering where the ore is ignited. The fumes will be found very disagreeable, but it is safe to walk over the entire pile when fully ignited. There is no danger of suffocation, and no ill effects follow. Much arsenic in the ore might alter this. The writer has had no experience with such ores. As to the temperature of the top of the heap, it must be kept as hot as will permit a man to walk over it and work upon it for a few minutes at a time. And speaking generally, the covering on no part of the heap should ever become hotter than boiling water. When any part reaches that temperature, the thickness of covering is increased. Where sulphur melts upon the covering and trickles down it, the ore is fusing, and not roasting, in the region beneath.

If the covering has been gradually thickened to check combustion as the heap warmed up, at the end of seven or eight days nearly three inches deep of fines have been put upon the slopes, and upon the top nearly four inches deep of fines. Thereafter, it will be necessary about twice daily to search for parts unduly warm, and upon these put a little more covering. In about ten days, the heap will require no more attention, and, in about eleven weeks from the time of firing, will be ready to remove to the furnace.

The heap as built will contain something over 850 short tons. If the method as here detailed has been followed, and no part of the heap has been allowed to fuse, it should give not over twenty tons of ore requiring any further roasting. The remainder should be thoroughly roasted.

Speaking by averages, the material, after passing through a rock-breaker, will come out—ore, 82 per cent; ragging, 7 per cent; and fines, 11 per cent. Ore and ragging will readily roast, but there will always be an excess of fines. After laying out the plan of a heap, about eight inches deep of these fines are first put on it, and the wood is piled upon that. If they do not sufficiently roast under the heap, they will at least harden into a mass that may be broken into lumps and scattered through a heap for final roasting. Or the fines may be piled a foot deep on any unoccupied ground, and there remain until the mass hardens. It may then be broked up and scattered through heaps for roasting.

It is most economical to build heaps of the dimensions given. They may be made 20 feet by 50 feet and 5 feet deep above the wood, containing about 250 short tons and requiring ten weeks for roasting; but they will contain, after roasting, nearly as much half-roasted as a bed of 400 tons, and proportionately are more costly for fuel and attendance.

The skill in roasting comes in covering the heaps. This must be done well and in time. There is no reason to fear extinguishing the fire; for it is far better to do that than to let the heap fuse. Furthermore, it is really difficult to do.

At not less than nine different mines lying along the ore-belt, and between North Alabama and Central Vermont, has heap-roasting been practiced. And at only two neighboring mines lying in Central Vermont can it be said to have entirely succeeded. As a type of the other seven, we shall not be far wrong in taking one of them, results at which Dr. Egleston gives in his paper, "Investigations on the Ore Knob Copper Process" (American Institute of Mining Engineers, May, 1881). At these works, he writes, "About three fifths of each heap are roasted," the remainder going into other heaps for re-roasting. His analyses show that the roasted ore contained from 6·76 per cent to 7·64 per cent of sulphur.

The first really good results in this country were obtained at the Ely mines, in Vershire, Vt., when under the management of William H. Long. He succeeded so perfectly in roasting the ores that all of each heap went directly to the furnace. He made no failures. And by his advice, the method as here detailed was adopted at the Elizabeth mine, in Strafford, Vt. At these works the entire heaps are smelted, the fines being transported separately and weighed in due proportion into each charge. None of the ore requires re-roasting. The heap just smelted there was a fair average. It contained 380 tons, and the sample of it gave 4·62 per cent of sulphur by the method of oxidation with fuming nitric acid. Another determination, by fusion with niter and soda, gave 4·61 per cent of sulphur. The sample was an average of the entire heap, except the covering of fine ore, which, however, was mostly smelted with the remainder. The ores are pyrrhotite with chalcopyrite, carrying about 33 per cent of subphur, and nearly 6 per cent of copper, and are very basic.

W. G.

STRAFFORD, VT., Dec. 1.

NOTES ON LIXIVIATION.

Written for the Engineering and Mining Journal by Ottokar Hoffmann, San Francisco, Cal.

Additional Chlorination after the Ore is Discharged from the Furnace.—If silver ores which have been subjected to a chloridizing roasting are left in a pile, after discharge from the furnace, they will retain a dark-red heat for many hours, during which time the process of chlorination continues. Mr. Stetefeldt made very interesting observations in this matter with the ore of the Lexington mine. The ore is of such a nature that only about 47 per cent of the silver can be chloridized in the shaft of the Stetefeldt furnace. Mr. Stetefeldt removes the ore from the furnace to the cooling-floor, where he leaves it for twelve hours in a red-hot state. He thus gains an additional chlorination of over 43 per cent.

That chlorination continues after the ore is discharged from the furnace, if left in a red-hot state, is well known; but that such an enormous gain can be obtained by it, and a chlorination of 47 per cent be increased to 90, is remarkable and very interesting. It seems, however, that if the roasting is carried on in the furnace to a high percentage, say from 85 to 88 per cent, the additional gain does not amount to more than one or two per cent, and this is mostly obtained in the first few hours, while, if cooled with water, especially in presence of chloride of copper, the chlorination will quickly increase. If the ore does not contain much copper, I use part of the concentrated base-metal solution from the leaching-vats to cool the ore and to improve the chlorination considerably. The proper way, therefore, is to let the red-hot ore lie for about two hours, then to moisten it well with water or with the chloride solution of the base metals, and not, as practiced in some lixiviation-works, where the ore is immediately spread on the cooling-floor, and then charged dry into the leaching-vats.

Another additional chlorination takes place in the vat during base-metal leaching which even exceeds that on the cooling-floor. I made this observation first with Silver King ore. That the lixiviation tailings from the vats are always poorer than those obtained in making the chlorination test from samples taken at the time of furnace discharge, was nothing new to me, but I attributed it to the additional chlorination on the cooling-floor. I found, however, that only a part of the gain has to be credited to the process on the cooling-floor, while the rest took place in the vat during base-metal leaching.

I give the results of roasting charge No. 952, which in its final chlorination represents the average of over 1100 charges:

	Per cent.
1. Chlorination at the time of furnace-discharge	85·30
2. After two hours hot on the cooling-floor, then moistened with water, the sample being taken at the time of charging the vat	88·3
3. Chlorination calculated from the vat-tailings after lixiviation	94·2

In this case, an additional chlorination of 3 per cent took place on the cooling-floor, and 5·90 per cent in the vat, or in all 8·9 per cent.

In another case, I found the roasted ore, when charged into the vat, to be only chloridized to 82·5 per cent, while the tailings, after leaching, showed a final chlorination of 95·3 per cent, or an additional chlorination in the vat of 12·8 per cent. As a matter of course, the loss in weight which the ore sustained during leaching had been ascertained in each case, and was brought into the calculation. The chlorination tests were made in a manner similar to the treatment of the ore in the vat, namely, leaching first with water, then with hyposulphite of soda.

If I am not mistaken, Mr. Stetefeldt made the observation that his chlorination tests showed higher chlorination if the sample was leached first with water, and then with hyposulphite of soda, than they did if the hyposulphite of soda was applied directly without previous leaching with water. The conditions for additional chlorination, however, are more favorable in a vat, where the ore is exposed during a longer time to the action of a more concentrated solution of base-metal chlorides, caused by the thicker layer of ore. The base-metal leaching with Silver King ore took from three to four hours, but only during the first half-hour was the outflowing solution of such concentration that it could possibly act on the silver.

Application of Steam in Chloridizing Roasting.—The advantage of using steam in chloridizing roasting is doubted by many metallurgists, because repeated experiments in California, Nevada, and Mexico failed to prove the same to be great enough to justify the increased consumption of fuel. At Monitor, California, I experimented with very rich concentrations, but without obtaining any marked improvement, either in regard to a diminished loss of silver or in regard to a more rapid and energetic removal of the base-metal chlorides. I had, however, a different and very interesting experience with the ore of the Silver King mine, in Arizona. The Silver King ore is very refractory, and consists of large quantities of zinc-blende, antimonial fahlore, peacock copper ore, galena, copper and iron pyrites, silver-copper glance, and native silver. The latter is so prominently represented that sometimes half of the assay value of the ore is present in the form of native silver. The zinc-blende predominates, and appears in all varieties—yellow, green, brown, and black. The gangue consists principally of heavy-spar, then porphyry and quartz. The average value during the year 1881 was $196.92 silver per ton—no gold.

I roasted the ore with 10 per cent of salt in the Hofmann furnace, which is a furnace fed by charges, and consists of a revolving cylinder provided with a fire-place and flue arrangement on both ends. The fire is kept alternately on one and on the other end, and the flame made to reverse its course through the furnace accordingly. In using this furnace, I had all the facilities to procure a uniform roasting at the lowest possible heat. But notwithstanding this precaution, the roasted ore showed the enormous loss of 38 per cent of the silver. I immediately made arrangements to pass in steam through the center openings of the furnace, and applied steam as soon as chemical action commenced. The injection of steam was continued during the whole time of roasting, and I had the satisfaction to find the volatilized silver reduced to a very small percentage. During 1881, the production of bullion showed an extraction of 89·2 per cent of the assay value. There was a loss of 6 per cent left in the tailings and of 4·8 per cent caused by roasting, dusting, and other sources of loss. Allowing 0·8 per cent for dusting and handling, the loss was thus reduced by the application of steam from 38 per cent to 4 per cent. It seems that steam is most effective if zinc-blende and antimonial ores are simultaneously present. It did excellent service in chloridizing the native silver.

Lumps Formed in Roasting.—If the salt is well mixed with the ore before charging the furnace, the lumps formed in roasting will be found to be almost as well chloridized as the finer part of the ore; and if they are porous and not burned to cinders, the chloridized silver may be easily extracted from them by lixiviation. In case of too many lumps, the silver extraction will be retarded.

Silver Dissolved by Base-Metal Chlorides.—A concentrated solution of base-metal chlorides will dissolve chloride of silver. It is therefore not advisable to use deep lixiviation-tanks, even if the ore permits free filtration. If the water passes through a thick layer of ore, it becomes so highly charged with the chloride salts that considerable chloride of silver will be dissolved. But, on the other hand, if the layer of ore is kept too thin, the operator loses much of the advantage of an additional chlorination in the vat. The best results will be obtained with vats 3 feet deep, and filled with ore to about six inches below the rim.

To prevent the base-metal solution from dissolving silver, I admit the water from below the filter bottom, and by slight pressure force it to ascend through the ore to the top. Thus, the concentrated solution accumulates above the ore, and the chloride of silver, together with some antimony and lead, is precipitated by dilution with a stream of water. If the diluted solution is then permitted to flow back, and out of the tank through the filter-bottom, the precipitated chloride of silver will remain on and in the ore, and is afterward extracted with the remainder of the silver. This operation delays the base-metal leaching about an hour and a half, and if such a delay should be objectionable, the dissolved silver can be regained by conveying the solution into large tanks, where the precipitation with water can be effected. After a vigorous agitation, the precipitate is allowed to settle, and the clear solution decanted. If enough precipitate has accumulated, it is removed to cotton cloth filters, strained, dried, and melted together with the silver precipitate in a cupelling-furnace. The value of the dried precipitate varies from one to three dollars per pound. If lime is used as a precipitant, a very base and bulky precipitate is obtained, which it is best to charge together with ore into the roasting-furnace.

Test to Ascertain the End of Silver Leaching.—As long as the solution of hyposulphite of soda is rich in silver, the precipitate with polysulphide of calcium is of a black-brown color; but this color changes, as the silver diminishes, into a light red-brown. The chloride of silver dissolves more easily in hyposulphite of soda than the sub-chlorides of the base metals and sulphate of lead: the solution, therefore will continue to show precipitate with sulphide of calcium long after all the silver has been extracted, especially if very diluted solution is used. It is impossible for even the most experienced lixiviator to tell by the color and appearance of the precipitate the time when all the silver is extracted. Still, it is important to know the exact time, in order to avoid a loss of silver by incomplete leaching or a loss of time by too long-continued leaching, in which latter case a great deal of base is unnecessarily added to the silver precipitate. I use the following simple and quick test: A tumblerful or two of the solution is precipitated with sulphide of calcium, the precipitate allowed to settle, the clear solution decanted, and the precipitate poured into a small paper filter. After being well washed with hot water, a part or all of it is introduced into a test-tube and boiled with nitric acid until

Digitized by Google

dissolved. Then the tube is held in cool water, to hasten the settling of the sulphur. The clear nitric acid solution is decanted from the sulphur into another test-tube, and tested for silver with a few drops of salt water or muriatic acid. The white precipitate is boiled with water to dissolve chloride of lead. As long as there remains a precipitate or the solution retains a milky appearance, leaching must be continued. It is of importance to wash the precipitate well with water before dissolving in nitric acid, as otherwise only a partial precipitation will take place with salt water, or none at all if only small quantities of silver are present.

Consumption of Sulphur and Lime.—The consumption of polysulphide of calcium depends on the amount of silver contained in the ore, and on the amount of base-metal subchlorides formed in roasting. Ores containing lead will consume more than those carrying copper. But, all in all, the consumption does not amount to much. Treating different kinds of base ore, I found it to be from 1 to 1·25 pounds of sulphur to the pound of fine silver produced, and about twice as much lime. At Silver King, during the year 1881, I produced 42,000 pounds of fine silver and used 43,149 pounds of sulphur, or about one pound to the pound of fine silver produced.

Filters for the Precipitate.—I use the following filtering arrangement, which will be found convenient, as it requires very little attention and handling: A square frame 6 feet by 6 feet is divided by cross-pieces into four squares 3 feet by 3 feet, and covered with unbleached cloth, forming in each square a filter-bag from 10 to 12 inches deep. Three of the dividing scantlings are provided with a cut 18 inches long and 1·5 inches deep. The precipitate from the tanks flows through a trough into the first filter, and, if this is filled, finds its way through the cut into the next, and so on until all four are filled. The set of filters is supported by frame-work above a square tank 6 feet by 6 feet and 10 inches deep, which is connected by a pipe with the pump-tank. According to the size of the works, there may be two or three such sets of filters. The flat tanks are made to communicate with each other by inserted pipes, and only one of them is provided with an outlet, which leads the filtrate back to the pump-tank. This outlet ought to be about 3 inches above the bottom, in order always to keep 3 inches of solution in the bottom of the tank, and to give the precipitate which may be forced through the cloth during the manipulation of washing, an opportunity to settle. At Melrose, Cal., I drained and dried the silver precipitate in a small centrifugal machine with good results, in a very short time. A larger centrifugal had been built for the Silver King mill; but it was built too light, and not well balanced, which made its use so dangerous that I had to abandon it after a few minutes' run. So far, no further experiments have been made with the centrifugal machine, which doubtless before long will take the place of the filters.

Treatment of the Precipitate.—After the main part of the solution has passed through the filters, which takes about three quarters of an hour, the precipitate remains on the filter in a soft, muddy condition, and has to be well washed with hot water. Then it is piled by means of a round pointed wooden spatula in cone shape in the center of the filter, and left to drain for a few hours. I do not press the precipitate, as this manipulation, without giving much advantage—especially if the precipitate has been well washed—is very unclean and troublesome, and causes considerable waste, but remove it direct from the filters into a small reverberatory furnace, where it is dried, and the main part of the sulphur burned off. To melt the precipitate in crucibles with iron and borax is expensive and is slow work. It does very well in small works; but if large quantities have to be melted, this ought to be done on a lead bath in a cupelling-furnace. For the Silver King works, I erected a German cupelling-furnace with this modification, that the hearth was stamped into a perforated cast-iron pan 5 feet 6 inches in diameter, and 10 inches deep, which afforded a free escape for the moisture. As hearth mass, I used three parts of pulverized lime-rock and one part of clay. In this furnace, I melted the precipitate in lots of 2000 and 3000 pounds, and obtained, after from eight to ten hours, silver bullion 995 fine, with a consumption of from 1 to 1½ cords of wood. I could use the same hearth for two, and sometimes three, meltings. The melting in a cupelling-furnace offers, besides cheapness and quickness, the advantage of obtaining fine bullion in one operation, which can not be done in crucibles if the precipitate contains lead.

THE LAW AS AFFECTING MINING AND METALLURGICAL INTERESTS.

Coal Lands in Alabama.—The following case is one of a large class that harass the official mind, growing out of the passage of the act of March 3d, 1883, exempting mineral lands of Alabama from the operation of the mineral land laws. The facts in brief are, that Yost made a homestead entry September 18th, 1869. He was unable to comply with the law as to residence, and so on September 26th, 1882, he made a cash entry under the act of June 15th, 1880. In the following December, a special agent reported to the Commissioner of the General Land-Office that the land contained valuable deposits of coal. A hearing was ordered; but the government abandoned the case and it never came to trial. September 1st, 1883, the commissioner took up the case and held the entry of Yost for cancellation, taking as a basis for this action the report of a special agent as conclusive evidence as to the character of the land, and deciding, as a matter of law, that the entry was not cured by the act of March 3d, 1883, because the entry-man had not resided upon the land to the date of his entry.

M. D. Brainard, Esq., counsel for Yost, in his appeal from the above decision to the secretary, says the case presents two questions for his determination: (1.) Has the Commissioner of the General Land-Office the lawful right to cancel a perfected land entry upon the mere *ex-parte* report of a secret agent without first allowing the entry-man a fair and open opportunity of proving his *bona fide*, and showing that the land is agricultural in character? (2.) Is the construction given by the commissioner to the act of Congress of June 15th, 1880, and March 3d, 1883, correct or erroneous? and argued that the cancellation upon a secret report was an arbitrary exercise of power and in direct violation of Article 5 of the Constitution of the United States. He quoted numerous authorities confirming the correctness of the latter position. Upon the second point, counsel shows that the entry of Yost was perfected under the provisions of the second section of the act of Congress of June 15th, 1880, which provides "that persons who have heretofore under any of the homestead laws entered lands properly subject to such entry . . . may entitle themselves to said lands by paying the government price therefor," etc. This is a remedial statute, and its legal effect was to excuse the default of residence under the homestead laws, and allowed the entry to be perfected by paying cash for the tract; the character of the entry remained the same; it was a homestead entry perfected by the payment of money instead of the usual five years' actual residence required by the general homestead law. And further, "being completely absolved from residing on the land, and excused for his former default, the claimant made application, paid the government price in money, perfected his homestead entry, and received his final certificate. Upon the face of the record, this entry was valid; and if there were any latent defects in it—if the land was mineral in character—the burden of proving that fact, by legal and constitutional methods, was upon the party assuming the affirmative of that issue, the government. The commissioner undertook, in his decision, to determine this question of fact upon the mere *ex-parte* report of a secret agent." . . . "If the land was mineral in character, and that fact was established in an open and lawful manner, the entry was voidable and subject to cancellation. This was the status of the entry prior to March 3d, 1883. . . . Said act abolished all distinction between mineral and agricultural lands in Alabama, and classified all of the lands in that State as agricultural in character."

The decision of the commissioner, and that of the secretary, are given in full below, by which it will be seen that the latter reverses the former:

COMMISSIONER'S DECISION.

REGISTER AND RECEIVER, MONTGOMERY, ALABAMA:

GENTLEMEN: I have this day examined Frederick C. Yost's cash entry No. 17,800, covering the S. ½ of the S. E. ¼ and the N. E. ¼ of S. E. ¼ of Sec. 14, Tp. 21 S., R. 4 W. The records of this office show that Yost entered the land September 18th, 1869, per homestead entry No. 1857. This entry was canceled by this office for abandonment February 27th, 1879. September 26th, 1882, the same party made his cash entry No. 17,800, under the second section of the act of June 15th, 1880.

Special Agent A. A. Mabson, having investigated the case under instruction from this office, states in his report, dated December 8th, 1882, that the land lies in the Lower Cahaba coal-field, and is in the locality where the finest grade of coal in the State is found; that there is an opening in Section 14, above referred to, where mining operations were carried on as long ago as during the late war, and that the tract in question is exceedingly valuable for its coal. He also says that the claimant never lived on the land. The mineral character of the land is clearly shown by the agent's report, as well as the fact that the claimant has not complied with the homestead law. The second section of the act of June 14th, 1880, expressly excepts from its provisions all lands which were not subject to entry under the homestead law, and as the coal lands in Alabama were at the date of the cash entry reserved from the operation of said laws, the entry under consideration was improperly allowed, the land not being of the character subject to such application. It follows, therefore, that the entry can not be passed to patent, unless it is done under or by virtue of the provisions of a later act of Congress. The act of March 3d, 1883, which is the only one upon the subject, confirms or authorizes the patenting of homestead entries made in good faith, where the claimants have complied with the homestead law in all respects except as to the provisions relating to mineral lands.

As the claimant in this case has not complied with the homestead law in regard to residence on the land, the entry is not embraced in the confirmatory provisions of the act of March 3d, 1883.

Mr. Yost's entry is therefore illegal, and it is accordingly held for cancellation. You will notify him that he will be allowed sixty days for appeal. Very respectfully, N. C. MCFARLAND, Commissioner.

SECRETARY'S DECISION.

DEPARTMENT OF THE INTERIOR,
WASHINGTON, D. C., November, 1883.

THE COMMISSIONER OF THE GENERAL LAND-OFFICE:

SIR: I have considered the appeal of Frederick C. Yost, from your decision of September 1st, 1883, holding for cancellation his cash entry No. 17,800, Montgomery, Alabama, made September 26th, 1882, upon the S. ½ of S. E. ¼ and N. E. ¼, of S. E. ¼ 14, 21 S., 4 W.; under act of June 15th, 1880 (21 Stat., 237), the land having been originally entered by him as a homestead September 18th, 1869. The only objection suggested by you is the fact that, after examination by a special agent, and in December, 1882, the land was reported to contain coal, and a hearing was ordered to determine the value of the alleged deposit. This hearing was subsequently dismissed by the register and receiver, and no final issue has been tried. It is claimed that the Act of March 3d, 1883 (22 Stat., 437), excluding the mineral lands in Alabama from the operation of the mineral land laws, had the effect to remove the necessity of further inquiry from entries of this class, consummated prior to its passage, and to confirm the same.

This construction has, to some extent at least, been favored by the department, and I do not think further action is required in a case like this, especially where an investigation has already been discontinued at the instance of the government, and no bad faith has been shown by proper hearing to attach to the claimant in the matter of his entry. Your decision is reversed. H. M. TELLER, Secretary.

Alleged Coal Lands—Instructions.—A special agent of the General Land-Office reported certain tracts in Colorado to be coal lands, whereupon the commissioner instructed the local officers to note the same in their tract-books, and "in every case of entry (not under the coal land law) for these lands where proof of settlement and cultivation is not required, such as additional homestead entries under the statutes for the benefit of soldiers and sailors, before issuing a certificate as a basis for a patent, a hearing must be had to determine the character of the land, after due published notice, according to the method prescribed in the circulars of this office relating to lands returned by the surveyor-general as mineral. In cases of pre-emption and homestead proof, the hearing as to the character of the land may be had at the date of proof, in accordance with the present practice; but in the notice of intention to make proof, notice must be given that testimony will be taken to determine the question as to whether land is or is not mineral in character, and copy of the notice

Digitized by Google

must be posted on each lot or 40-acre subdivision thereof. Parties appearing at the time appointed for the hearing, to testify to mineral value of the land, should be allowed to give testimony and cross-examine witnesses as in contested cases. Existing instructions authorizing hearings in some instances as to the character of tracts in respect to the agricultural or mineral value are modified hereby, so far as the lands in question are concerned.

Taxation of Stock in California, the Property being in another State.—Shares of stock in a mining corporation whose principal office is in California and whose entire property is in another State are, when held by citizens of California, taxable in that State, although the corporation is obliged to pay taxes on its property in the other State, according to the decision of the California Supreme Court in the recent case of San Francisco *vs.* Fry.

THE STEEL FOR THE MONONGAHELA BRIDGE, PITTSBURG, PA.*

Every heat of steel was tested and its quality determined before any more work was done to it. For the compression members and pins, the steel was required to stand the following tests on specimen bars $\frac{7}{8}$ inch diameter: Elastic limit, 50,000 to 55,000 pounds per square inch; ultimate strength, 80,000 to 90,000 pounds per square inch; elongation in 8 inches, minimum, 12 per cent; reduction of area at fracture, minimum, 20 per cent; cold bending, 180 degrees around its own diameter without crack; cold punching of holes in flat 3 by $\frac{5}{8}$-inch bars, $\frac{3}{16}$ inch from the edge without crack or distension of metal.

All specimens and shapes were required to be finished at nearly the same heat, as it was observed that rods finished at a lower heat would give higher tension results than samples of same steel finished at a higher heat. The Andrew Kloman firm, in Pittsburg, had contracted to procure the steel and to furnish the steel shapes. The intention was to use Bessemer steel for the compression members; a large lot of Bessemer steel was tested, but few samples were found to stand the desired tests. The difficulty seemed to consist in controlling the uniformity of the steel within close limits for quality and strength. After a while, the attempt was given up and open-hearth steel was substituted. No trouble was then experienced in getting a uniform grade of steel of prescribed quality. The top chord sections consist of four leaves, which were originally designed to be each a 20-inch steel plate with 4 by 4-inch angles for flanges. In ordering the steel, it was discovered that enough plates of that width could not be procured in the required time. Therefore, the chord sections were changed to 10 inch and 12 inch steel plates, with 4 by 4-inch angles, composed as shown in the drawings.

Notwithstanding the great care used, the finished plates and angles were by no means a uniform product. Accordingly as they in rolling were finished at a higher or lower heat, they would have different degrees of hardness. Steel plates and angles finished at a lower heat had a smooth surface, and the noise of punching them resembled pistol-shots, while plates finished at a higher heat had a rougher surface, and there was hardly more resistance to punching than in wrought-iron.

The specification for riveted steel work provided that the punched rivet-holes, three quarters of an inch diameter, should in the assembled parts be enlarged to one inch diameter by reaming. The time for the delivery of the steel work growing short, the question was considered whether the reaming of the holes could be avoided, to hasten the completion of the work at the shops. Messrs. Kellogg & Maurice, of Athens, Pa., had the contract for this part of the work.

To that end, the following experiments were made: Ten specimens were cut from the same steel plate a quarter of an inch thick; one specimen was tested, to ascertain the tensile strength of the steel specimen. The nine other specimens, all alike in form, were prepared, for the purpose of ascertaining the effect of punching holes, of punching and reaming, and of drilling. The tests were expected to show the amount of reaming required, and whether any annealing effects from the hot rivet on the injured steel around the punched hole could be observed.

The conclusion from the tests was, that the injured steel (of the quality used in this instance) around the punched hole was in part restored by annealing in contact with the hot rivets, the size of which was large in proportion with thickness of steel plates and angles as used in the chords. The reaming of the punched holes to a greater extent than to make the rivet-holes smooth and straight was therefore dispensed with, and a reduction in the price for the finished work agreed upon. The steel pins are 6, $5\frac{1}{4}$, 4, and $3\frac{1}{8}$ inches in diameter. The same quality of steel as for the compression members was used for them; they were forged from solid steel billets, and turned to size. No appreciable difference in the hardness of the metal in the pins was observed.

For tension members and rivets, the steel was required to stand the following tests on specimen bars five eighths of an inch in diameter: Elastic limit, 45,000 to 50,000 pounds per square inch. Ultimate strength, 70,000 to 80,000 pounds per square inch. Elongation in 8 inches, minimum, 18 per cent. Reduction of area at fracture, minimum, 30 per cent. Cold bending, to a loop 360 degrees around its own diameter, without crack. Cold punching in 3 by $\frac{5}{8}$-inch bars of 1-inch rivet-holes, one eighth of an inch from the edge without crack or distension of metal. Open hearth steel of the above and uniform quality was obtained without trouble.

The eye-bars were made by the Kloman process—that is, the bars were rolled from billets between reversible and adjustable rolls, in such a manner as to leave the ends thicker than the bar. The ends were then spread and forged to the proper shape of the eye under a steam-hammer. The heaviest steel bars for this bridge were 28 feet $6\frac{1}{2}$ inches long, center to center of eyes, and $1\frac{1}{16}$ inches thick. All steel billets and all steel bars required very close inspection for flaws, the detection of which was sometimes difficult. It has been stated that, for the detection of flaws in steel or iron, a magnetic needle had been used with success, though the manner of its use the writer has not heard stated. A device for the certain discovery of flaws in steel bars is certainly needed. Where the solid metal sections are proportioned very economically to the work they have to do, flaws are a source of great danger, especially in attenuated steel structures; flaws in wrought-iron are more likely to happen in the direction of the fiber, but in steel they can as well happen crosswise to the direction of the tension strain as any other way. Three steel bars 9 feet long between centers of eyes, and 4 inches by $1\frac{1}{16}$ inches in section were tested, to ascertain the effect, if any, of annealing the finished bars.

The results were as follows:

	Bar A. Annealed.		Bar B. Not Annealed.		Bar C. Not Annealed.	
	Eye.	Eye.	Eye.	Eye.	Eye.	Eye.
Diameter of eye in inches	9	9	$9\frac{1}{16}$	$9\frac{1}{16}$	10	9
Least cross-section of eye in sq. inches	5·72	5·82	5·83	5·72	6·83	5·77
Excess of metal in eye over bar, p. c.	29·4	31·7	38·1	35·5	57·7	33·2
Reduction of area in eye at pin-hole, p. c.	7·9	3·6	3	3·2	3	3
Elongation of pin-hole in inches	0·4	0·72	0·45	0·44	0·38	0·4
Average section of bar in square inches	4·42		4·22		4·33	
Average reduced area after test in sq. in.	3·96		3·97		3·89	
Reduction in per cents	10		5·1		10	
Reduction at fracture, per cent	43·87		37·5		37·55	
Elongation of whole bar, per cent	10·5		10·3		11·1	
Elongation for 12 in. near fracture, p. c.	24·6		23·2		22·1	
Elastic limit per square inch	43,140 pounds.		45,360 pounds.		40,940 pounds	
Ultimate strength	74,310 "		78,180 "		73,760 "	

All pin-holes were $3\frac{1}{16}$ inches diameter.

Pin-hole in one eye of bar C was bored one quarter inch out of center-line of bar, and accounts for its lower ultimate and elastic limit.

A specimen from the same heat of steel, of which the above bars were made, showed on a three-quarter inch round: Elastic limit, 46,389 pounds per square inch. Ultimate limit, 78,898 pounds per square inch. Elongation in 8 inches, 18 per cent. Reduction, 30·2 per cent. The net section of the heads through the pin-holes for all eye-bars being at least 50 per cent more than the bars, and the good effects from annealing being doubtful in the above tests, it was not thought necessary to anneal the steel bars. For steel rivets, the above quality of tension steel proved very suitable. The rivets were tough and tenacious. It was, however, observed that the manufactured rivet-heads would easily break off with few blows, the fracture in each instance showing a fine granulated appearance. Rivet-heads, however, made by hand or riveting-machine were very tough, and could not be broken off; they had to be cut off. The cause for the brittle rivet-heads was supposed to be the upsetting by blows, in forming the head at a high heat in dies, producing sharp corners under the rivet-head and around the rivet-stem.

* From a paper by G. Lindenthal, read at the annual meeting of the American Society of Civil Engineers.

THE USE OF STEAM IN THE BESSEMER CONVERTER.

Captain William R. Jones, of the Edgar Thomson Steel-Works, Braddock, Pa., in the specification of patent No. 287,687, dated October 30th, gives an historical sketch of the causes leading to the invention, and a well-written account of its advantages and special applications. The same subject, it will be remembered, was recently dwelt upon by Mr. Robert Forsythe, in this paper on the South Chicago plant, read before the Troy Meeting of the American Institute of Mining Engineers, a full abstract of which was printed in our report. Captain Jones says in his specification:

In the early practice of the Bessemer method for reducing cast-iron to homogeneous malleable iron or steel (ingot metal), the charge of pig metal in the converter did not much exceed five tons in weight. Owing to the insufficient power of the blowing-engines, and to other causes, it was not feasible to work any greater weight of metal at one blow, and even then the conversion of the charge, which was obviously dependent upon the quantity of oxygen supplied, usually consumed twenty-five minutes, and frequently required much more time. In the interval between heats, the crude pig metal tapped from the cupolas accumulated in the collecting-ladles and steadily fell in temperature. For this reason, but more especially because of the long duration of the treatment, it was necessary that the pig metal should contain a high per centum of silicon (usually about three per cent), or of other heat-developing material—such, for example, as manganese—which would burn out in the course of the subsequent blow, and keep the metal in condition best adapted to effect its satisfactory conversion. The "chilling" of the charge was the evil to be guarded against, and the presence of the silicon or its equivalent in high proportion was an essential precaution. If the metal should for any reason become overheated, as sometimes occurred, then a small amount of scrap—such as rail ends, butts, clippings, etc.—not to exceed five hundred pounds, and rarely that much, in weight, was added to the charge, either in the converter or in the casting-ladle, to reduce the temperature, and thus to save the ingot-molds from being "cut" by the hot metal. In the latter stage of the art, the improvements in blowing-engines and other machinery and the increased capacity of the converter and of the tuyeres have enabled the operator to work ten tons and upward of metal at a single heat and to effect its conversion in from eight to fourteen minutes (rarely beyond the latter), where some twenty-five minutes were necessary before to reduce five tons. This marked difference in the amount of the charge, the rapidity of conversion, and the frequency of the heats has been attended with other important changes. There is now but brief chance for the converter to cool or for the metal to accumulate in the collecting-ladles. The metal is oftentimes tapped directly from the blast-furnace, and hence the conditions are all such as tend to make the temperature higher and constantly increasing as successive charges are worked. The crude pig-iron is no longer high in silicon, but is preferably made to contain less than one per cent, though this may not be diminished too greatly in the working of the blast-furnaces without risk of introducing a hurtful per centum of sulphur in the metal. Despite all precautions, the energy and rapidity of the converter reactions frequently develop an overheated condition of the charge, which is attended by an emission of peculiar smoky vapors that obscure the flame so that the operator may not accurately determine when the blow should end. The overheated metal attacks the molds in casting and speedily destroys them. To add scrap or clippings of metal, either in the converter or casting-ladle, as may be necessary and was practiced before, has become troublesome, expensive, irregular in its results, and not always effective. From two thousand to seven thousand pounds are now frequently added

Digitized by Google

to the charge, which, quite aside from loss of time and uncertainty in determining what amount is requisite, involves the consumption of materials sometimes not conveniently obtained and having quite as high a market value as the finished metal itself. Besides, there is much risk of introducing objectionable or inferior grades of metal into the charge.

My invention is designed to obviate the use of this large quantity of clippings, etc., and to regulate the temperature of the charge at any stage of the conversion in a simple, expeditious, and inexpensive way, so that "over-heating" is prevented. The flame is kept clear and free from obscuring vapors, so that the operator may determine with great nicety when the blow should end, and the ingot-molds are no longer subject to the destructive attacks of "hot" metal. This object I have accomplished by the use of steam, in conjunction with the air-blast, in the following manner:

When, at the beginning of the operation, the metal has been run into the converter and the air-blast has been turned on in the usual manner, steam is admitted from a pipe connected to the blast-pipe, and passes with the air through the tuyeres until the temperature of the metal is sufficiently reduced to insure a clear flame, when the steam will be shut off and the air-blast continued alone until the completion of the blow. The length of time during which steam will thus be admitted to the converter will depend upon the size of the pipe delivering the steam, as well as upon other conditions, such as the nature of the metal, the pressure and volume of the air-blast, etc.; but I have found in practice that in working a ten-ton converter with steam delivered at about fifty pounds pressure through a pipe of one and one half inches in diameter, the steam may be forced with the air about six minutes, or about one third to one half the length of the blow. It will also be found of advantage in some cases to inject steam with the air-blast for a short time just before the completion of the blow, if the heat of the metal is shown by the flame to be excessive, and, in fact, the steam may be introduced at any time when the appearance of smoky vapors or other indications in the flame familiar to the operator show that the metal is becoming too hot. The skilled operator will readily understand, however, at what stage and for how long a time the steam may be advantageously employed, depending, as it must, somewhat upon the varying conditions under which the work is performed.

Instead of using the steam at the commencement of the blow, it may be introduced first at some latter stage, or, again, may be used continuously throughout the entire period of conversion in connection with the air-blast. Again, in lieu of steam, it may be expedient to introduce a spray of water in finely-divided (atomized) condition, together with the air-blast, though, as the chilling effect is much greater than where the steam is employed, the more equable action of the latter makes its use preferable in practice, as heretofore indicated.

When scrap is used to chill the charge, the tendency is, as before stated, to reduce the per centum of silicon in the pig metal to the lowest working limit, because thereby less heat is developed in the converter and the amount of scrap to be added is correspondingly diminished; but in so far as the silicon is reduced, there is danger of more and more sulphur passing into the iron while it is being smelted in the blast-furnace; hence it is an obvious and important advantage of the present invention that it allows for the use of a grade of pig metal which shall be high enough in silicon to uniformly avoid the presence of an objectionable per centum of sulphur, and yet which, despite its greater heating capacity, is under the easy control of the operator, who may quickly and cheaply counteract any harmful increase in temperature that may develop during the blow.

The skulls from the ladles, butts from the ingots, and the like, which ordinarily accumulate about the mill, may be utilized by re-melting with subsequent charges in the converter, as heretofore; for while the present invention enables the scrap metal to be entirely dispensed with, there is nothing detrimental in such additions. Besides, the scrap metal of a single mill is but a minor percentage of the additions which the invention is designed to save.

THE DAFT ELECTRIC RAILROAD.

A trial of the Daft electro motor for propelling railroad cars took place at Saratoga, N. Y., on November 24th last.

In the Siemens Berlin electric roads, the current to operate through the motor is sent through wires overhead, it having been found inconvenient to so insulate the track as to use the rails therefor, and also because, unless properly covered and insulated, the rails would be highly dangerous to other travel. Mr. Daft, by a subdivision of his dynamo, claims to obtain a current of such low tension that all danger from contact is avoided; but the insulation was by no means thoroughly effected by his sending the current through a third rail in the center, of which the fastening spikes were removed from the rail by a strip of vulanized rubber. Then, although one could touch the rails without feeling any unpleasant shock, it was very evident that many were temporarily "excited" in crossing the tracks on the occasion referred to, while no less than four horses fell on the track from the effect of the current, and had to be helped off.

The actual performance consisted in the hauling by a two-ton motor of a five-ton car, with probably five tons more in weight of passengers, a distance of a mile and an eighth. This was up a grade of 70 feet to a mile, with one sharp curve, and was effected in eleven minutes. On the return, the motor was thrown from the track, and several who were on it had narrow escapes; but the accident was due to a make-shift rope coupling, and did not involve Mr. Daft's principle at all. The dynamos at the factory for generating the current were 500 feet from the track, and were operated by a 30 horse-power engine. The motor itself seemed entirely too small and light for the work expected from it, the dynamos thereof and connections occupying a box only about four by six feet. The current for these is taken up from the central track by a contact-wheel, which transmits it to a receiving dynamo, and thence by connection with a steel belt through the axles to the outside rails causes the revolutions. The apparatus is easily operated, and evidently was entirely under control. Mr. Daft was warmly congratulated on the degree of success obtained, and most of the numerous party present were confident that the trial was a proof of the practical success of the system.

THE PUMPS OF THE BINDWEIDE MINE, GERMANY.

(WITH SUPPLEMENT.)

The pumps chosen were those designed by Carl Kley, of Bonn, repeatedly tried with good success. As will be seen by a reference to the drawings in our Supplement, they have the form of a reversed pressure pump, the plunger being a stationary suspended pipe, while what is the cylinder in ordinary pumps moves. The piston-rod passes through the entire pump, being attached at the lower end to a cover which is removable. The pumps lift the water on the upward stroke of the rods, and their advantage is, that therefore the latter are strained in tension instead of compression, that the impurities in the water which have a tendency to settle can not so easily get into the stuffing-box, and that the latter is more easily packed. The mud gathering in the plunger may be readily got rid of by unscrewing the bottom, though it would seem that possibly a simpler way would be to provide a cock sufficiently large to flood it out. In order to provide as large a suction as possible for the passage of the water, three beat-valves of the Thometzek type were chosen, packed with leather rings. As the drawings show, they are easily got at.

The pump-rods are made of cast-steel, the purpose being to make them as light as due regard to safety will permit—an object attainable only by using the best material. Under the circumstances, the rods are strained only in tension, the maximum being 6·6 kilograms per square millimeter. They were made 105 millimeters in diameter immediately below the mouth of the shaft, 96 millimeters to the first deep level, 80 millimeters to the second level, and are to be 50 millimeters in diameter below that level. In order to be able to provide guides at any point, and to make sure that the material of the rods was not defective at any point, the rods were turned off the slide-guides used. The manner in which the different sections of the rods are connected is fully shown in detail in the drawings, so that it is not necessary to go into any further description of them.

A WATER-GAS FURNACE AT ELGIN, ILLINOIS.*

By P. Barnes, Joliet, Ill.

In a paper recently read before the Institute by Mr. W. A. Goodyear, a useful presentation was made of the subject of the production of water-gas on a large scale, by the use of a regenerative form of apparatus. By way of supplement to that paper, a brief statement of the details of a plan which was carried out at the works of the Elgin National Watch Company at Elgin, Ill., may be of interest, although the ultimate result of the working of the producer was not successful or satisfactory. This company had decided to build a gas-works for the supply of illuminating gas to its factory, on a much larger scale than that of the petroleum works which had very successfully supplied the smaller buildings for many years, and in March, 1882, the material for a gas-making cupola furnace was purchased. A few weeks later, it was decided to make the attempt to burn the gas under the steam-boilers of the establishment, and a second set of material was ordered.

In July, 1882, when the writer took charge of the work of construction, it was agreed, after a study of the probabilities of the situation, to make an attempt to utilize the waste heat developed in the process for preheating the air-blast and the steam used to the highest possible point, so that the fullest practicable limit of economy should be reached. This was believed to be the more needful, because of the obvious requirement that the gas should be furnished at the least possible cost, to meet the competition with coal fired directly under the boilers. The material which had been purchased was utilized as fully as it could be in building two fire-brick stoves, and the fire was put in a rectangular fire-box, which was attached to the stoves by short direct flues. The plans for this work were completed in August, 1882, and the furnace was set at work in February, 1883.

It was soon found that, although the proposed preheating of the blast and of the steam was very fully accomplished, yet the shape which had been adopted for the fire-box was not such as to secure the intense concentration of the heat needed to secure the complete fluxing of the furnace which had been undertaken. It was also found that the chilling of the slag, which was run down in considerable quantities by the steam blown in during the gas-making, was so complete that it became quite unmanageable, and that it would lodge in the base of the fire-box below the line of fusion, and also above this point, with so little fuel remaining in or near the masses of slag that they could not be remelted when the blast was turned on again. This action of the steam in cooling the slag was anticipated, but the trial was thought to be worth making.

A considerable quantity of gas was made in the furnace with the regenerative fixtures as first erected, the holder which had been provided for the storage of the illuminating gas being used for the fuel-gas during the trials which were made. This was burned under the boilers, using simple perforated iron pipes for burners. A considerable evaporation was reached, but it was found that, in order to compete with direct coal firing, even with the market price then current for coal used under the boilers, of $5 per ton, the gas must be furnished for decidedly less than five cents per thousand cubic feet, even if the cost of labor, as compared with direct firing, were to be wholly omitted in making up the estimate.

The saving of the waste heat was found to be very complete, the products of combustion and the water-gas both escaping from the apparatus at a temperature very close to the boiling-point of water. It was found that the splintering of the brick-work in the lower part of the fire-box, due to the removal of the very stubborn clinkers which were formed, would lead in any event to a very short life of that part of the apparatus as then constructed, and in view of some other important local reasons it was considered advisable to abandon the regenerative fixtures, and the expectation of using the gas under the boilers. The furnace was then rebuilt and fitted up for making illuminating gas only, upon the plan which had been used for some years in Chicago under the patents of Mr. T. G. Springer. The whole was put into very successful operation in July, 1883.

*Read at the Troy Meeting of the American Institute of Mining Engineers.

THE LEAD PRODUCTION OF COLORADO.

The Leadville *Herald*, in a recent issue, prints a timely article on the production of lead in Colorado, from which we make the following extract:

During 1882, Leadville shipped to the Eastern refineries 43,000 tons of lead in base bullion. During that year, Grant's large works were in operation until the latter part of May, and the Elgin smelter the last half of the year. The remaining smelting-works were in blast with remarkable regularity during the entire twelve months.

During the first ten months—up to November 1st, 1883—the product of the Leadville smelters is still 4500 tons in arrears of the product for the corresponding period of last year. During the first four months of the year, the Elgin smelter was idle. The Harrison works, by the destruction of their establishment in the spring, and inability to secure ore later on, lost about three months' time. The La Plata smelter, which started up last week, also lost several months. At present, all the works are in full blast, with the exception of perhaps one small furnace at the La Plata. As a consequence, it is reasonable to suppose a slight gain will be recorded for December, over the product of the corresponding month of last year, leaving the year's work of this camp to sum up about 39,000 tons of lead, against 43,000 tons during 1882.

During the year 1882, there were shipped from Leadville 90,102 tons of ore. During the first six months of this year, the shipments amounted to 75,100 tons, and for the year it will be safe to place them at 140,000 tons. Compared with last year, these figures will show an increase in the ore shipments of 50;000 tons. Estimated on the usual basis of twenty per cent of lead, this exhibit would show that Leadville will ship lead in ore, in excess of the same class of shipments last year, 10,000 tons, from which, after deducting the 4000 tons of lead that the Leadville smelters will fall short this year of the production of 1882, leaves a net gain in the lead product of the Leadville District of 6000 tons. This, however, is believed to be above the actual figures, as much of the ore shipped during the past six months was iron ore, which was sent to Denver, Pueblo, and Salt Lake City, and devoid of lead, being used chiefly as a fluxing material, though carrying from six to fifteen ounces in silver to the ton. Making some allowance for this feature, say 2000 tons of lead, and we have an estimate of the entire product of lead of this district for 1883, which is 47,000 tons, or only 4000 tons in excess of the yield of 1882—excluding in the calculation 90,000 tons of ore as an offset on an equal amount shipped last year, and not taken into consideration in the above computation. In these figures are included what lead ores from neighboring camps found their way into the hands of Leadville smelters and ore-buyers, which this year was much less than for two years past.

To carry these estimates out, and include the product of the whole State, is a more difficult matter, and one that can not be done with as much assurance as the calculation on Leadville. Last year, we placed the product of lead for Colorado at 70,000 tons, and the refiners credited this State with 68,000 tons, when several months later they submitted a statement of their year's work to a government statistician.

The 90,000 tons of ore shipped during 1882 were estimated to contain twenty per cent of lead, or 18,000 tons. Taking the ore shipped from Leadville this year, 140,000 tons, and estimating it to contain eighteen per cent of lead, net, it would give a yield of 25,200 tons; which, added to the actual smelters' product of 39,000, would give a total for Leadville of 64,200 tons. Added to this amount the ore shipments from Eagle County, containing 4000 tons; ore and bullion shipments from Summit County, 2000 tons; ore and bullion shipments from Chaffee County, 3000 tons; and from other portions of the State, 2000 tons, aggregating 11,000 tons, which, added to the amount previously accredited to Leadville makes the estimated total lead product of Clorado 75,200 tons. A great quantity of ore, the lead of which has been calculated and is included in the above figures, will, however, not be smelted between now and January 1st, so that probably 73,200 tons will represent fairly the amount of lead converted into bullion during the year. An approximate proof can be found of this in figures representing the probable yield of the different smelters in the State. Leadville, 39,000 tons; Denver, 15,000 tons; Pueblo, 14,000 tons; Cañon City and lesser smelting towns, 5000. Total for the year, 73,000 tons, an excess for the State over 1882 of 5000 tons of lead.

As an offset on this increase, we learn that the Missouri and Mississippi River valleys are still eight thousand tons in arrears of their production for the corresponding period of last year, and the Nevada mines also show a decided falling off. New Mexico shows a gain of a few thousand tons, also Idaho, with probably a small increase in a few other territories. From these figures it would appear that, if there is a stock of twenty thousand tons of lead now in the market, the consumption is not as great as has been reported, and will not show a material increase over last year.

The excess of lead now in stock and seeking a market is not definitely known, but unquestionably quite large. Until the bulk of this is worked off and consumed in the industries, there is no hope for the price of the metal attaining what might be considered fair figures. In order to permit the consumption of the present stock, the production must be temporarily decreased. A united action of the lead-producing mines in this direction can not be secured. They are too numerous to pool their issues, as the corroders have done, and as a consequence the mines will continue competing with one another in the production and sale of lead. No one mine or district will voluntarily suspend production to help the market, and see others take advantage of the situation. The weaker must therefore be forced to the wall. This is a task that will not be accomplished without a struggle. It is therefore not likely that the product will be reduced immediately, or before a greater decline in the price of lead is experienced. This being the situation, Leadville must prepare herself to contend with other sections to furnish lead just as cheap as can be supplied by the mines of Missouri, Utah, and Nevada. From all reports, Missouri mines are already crowded to the wall, and a great many have closed down. The Utah mines are favored by railroads in the matter of freight rates, so that at present they possess an advantage over Colorado that our mining interest are now attempting to have equalized by a proportionate reduction on freight rates from Colorado. If this can be secured by a proper representation to the railroad companies of the mutual benefits that will result from a concession on their part, Leadville and the State will be enabled to hold out until better prices are again to be obtained; otherwise, the stability of the lead mining districts is doubtful. The present decline in lead and the exorbitant freight rates, together with the expense of desilverizing, have reduced the value of lead on board of cars in Leadville to $28 per ton—doubtless less than it is worth at any other smelting center in the United States. This being the situation, it is plainly to be seen that Leadville and several other Colorado points have the worst of the present situation, and are fully justified in calling on the railroads and demanding the relief that is necessary to place them on an equal footing with other sections in the important matter of freight rates on bullion.

LIQUID FOR DETERMINING THE SPECIFIC GRAVITY OF MINERALS.—Nearly all natural minerals are heavier than water, and therefore sink in it. But when they are placed in a heavy liquid which does not dissolve them, some sink and others float. If two minerals of unlike gravity occur in the same rock, they can be separated by pulverizing the rock and putting them in a liquid intermediate in weight between both. A new liquid for this purpose has been devised by C. Rohrback, having a density of 3·57. According to his paper in *Wiedermann's Annalen*, it is an iodide of barium and mercury, and is prepared as follows: 100 parts of iodide of barium and about 130 parts of red iodide of mercury are mixed with about 20 c. c. of distilled water, shaken and heated on an oil-bath to 150 or 200 degrees C. until dissolved, and then concentrated until it will float a crystal of topaz. After standing several days, the clear liquid is decanted and filtered. It has a yellow color, boils at 145 degrees C., and refracts light strongly. It can be used for separating axinite, epidote, heavy mica, some garnets, and nearly all hornblendes; also olivine, orthite, nearly all members of the pyroxene group, saussurite, titanite, topaz, heavy tourmaline, vesuvianite, and basaltic rocks. In diluting it to obtain any special density, it is mixed with a dilute solution of the same, so as to avoid precipitation. After the separation, the powdered minerals are washed with a few drops of iodide of potassium.

FURNACE, MILL, AND FACTORY.

The Babcock & Wilcox Company reports the following sales during the four weeks ended November 24th. The figures given are horse-power: New York Steam Company, New York, 1250; Ponemah Mills, Taftville, Conn., 200; Maitland, Phelps & Co., New York (for export), 104; Arbuckle & Co., Brooklyn, N. Y., 208; Nathan R. Yewdall, Philadelphia, Pa., 104; McCracken, Stark & Co., Philadelphia, Pa., 35; Dager & Cox, Bridgeport, Pa., 104; Edison Electric Illuminating Company, Tiffin, O., 92; Edison Electric Illuminating Company, Mount Carmel, Pa., 51; Edison Electric Illuminating Company, Newburg, N. Y., 146; Edison Electric Illuminating Company, Hazleton, Pa., 92; Edison Electric Illuminating Company, Bellefonte, Pa., 82; William Lea & Sons, Wilmington, Del., 125; McCullough Iron Company, Northeast, Md., 104; W. W. Taylor, Havre de Grace, Md., 20; Westinghouse Air-Brake Company, Pittsburg, Pa., 92; Lucy Furnaces, Pittsburg, Pa., 832; Pittsburg Steel Casting Company, Pittsburg, Pa., 416; Black & Germer, Erie, Pa., 92. Total, 4149. The New York Steam Company, which is at the head of the above list, has now ordered 8999 horse-power of these boilers. The various Edison companies, including those in the United States, London, Paris, and Milan (Italy), have ordered 3356 horse-power. The business of the New York Steam Company is to convert the heating power of coal into steam, and distribute the same to its customers. The business of the electric illuminating companies is to first convert the heating power of coal into steam, and then use the mechanical energy of this steam to make light. With both of these businesses, the largest item in their whole expenditure is the cost of fuel. It is therefore very necessary for them to select the boiler which will economize fuel to the utmost extent.

The ground is staked off for the erection of the mill of the new Charter Iron and Steel Company, Limited, at Mansfield, Pa., and building will soon be commenced.

It is stated that the Pennsylvania Steel Company, at Steelton, will shut down its entire works early next year, on account of lack of orders. This stoppage, if it takes place, will be the first that has occurred in the history of the company.

William Tod & Co., of Youngstown, O., recently furnished the West Newton, Pa., mines with a hoisting-engine and drums, and are now preparing a set of double reversible hoisting-engines with 6 foot 6 inch drums, which will be the second outfit of this character furnished the Port Royal Coal and Coke Company, at Port Royal, Pa.

Hall's Automatic Feed-Gas Fuel Company has recently been organized in Chicago with H. V. Bemis as President and Treasurer; T. J. Wheeler, Vice-President; George Dickinson, Secretary; J. J. Hall (the inventor), Superintendent; and A. K. Tappan, Assistant-Superintendent. This company will manufacture Hall's improved automatic-feed furnace.

The articles of incorporation of the Volta Iron Company, Limited, have been filed for record in the recorder's office in Pittsburg. The object of the company is to deal in iron, its products, galvanized iron, and to galvanize iron. The capital stock is $300,000, and is held as follows: Philip H. Laufman, $52,500; Sarah B. McElroy, $52,500; Joseph M. Bigham, $48,333.33⅓; John Evans, $48,333.33⅓; J. J. Vandegrift, Jr., $24,166.66⅔; W. Batchelor, $24,166.66⅔; Herman C. Mechling, $50,000. The stock is divided into 3000 shares, and is valued at $100 per share. The Apollo Iron-Works has been consolidated with this enterprise.

The Omaha Water-Works Company has lately ordered of the Knowles Steam-Pump Works, of New York, a pumping-engine of five million gallons daily capacity. This pumping-engine will be of the compound condensing duplex design of Knowles's improved construction, and will take the place of some pumping-engines that have not proved powerful enough for the very exacting duty required in these water-works. The pressure which this new engine will have to work against will be equal to a head of nearly four hundred feet elevation.

No. 5 furnace of the Pennsylvania Steel Company, at Steelton, Pa., was recently damaged by fire.

Manager Watson, of the Cleveland Rolling-Mill Company's Central Furnace, has designed and put in operation an ingenious buggy, which will dump its load upon the bell much more effectively than does the old style. It is built on an angle of about 30 degrees, and empties by the swinging outward of the entire side.

The Cuyahoga Forge and Iron Company, Cuyahoga Falls, is placing in its works a new 20-inch train for the manufacture of Ostrander's patent mandrel rolled hollow bar, in either round, hexagon, or square shape. This hollow bar iron is used principally for the manufacture of sleeve-nuts for bridge and car purposes. Its present eight-inch train will be used as heretofore for the manufacture of its patent hollow stay-bolt bar.

The Cummer Engine Company has just completed an extension to its works which will increase the capacity of its machine-shop about twenty-five per cent.

Digitized by Google

Among some of the more recent orders of this company are the following: A pair of 16 by 30 engines for the Underground Electric Light Company, Philadelphia, Pa.; a 14 by 30 for the Wellington Milling Company, Wellington, Ohio; a 14 by 30 for Ballard & Ballard, Louisville, Ky.; a 14 by 30 for J. E. Hart, Jacksonville, Fla.; a 10 by 20 for Mr. Caleb Loud, paper manufacturer, Loudville, Mass.; an 18 by 36 for the Cypress Lumber Company, Appalachicola, Fla.; a 10 by 20 for E. M. McGillin & Co., a 10 by 20 for George Worthington & Co., and a 14 by 24 for Taylor & Boggis, Cleveland, Ohio; a 15 by 24 for the St. Louis Basket Company, St. Louis, Mo.; a 13 by 24 for Brose & Arnold, Evansville, Ind.; and a 20 by 42 for the Stearns Lumber Company, Neponset, Mass. This company deserves to be congratulated upon its success at the exhibitions this fall. Not only has it obtained the gold medal and the $100 special award for the best automatic engine at the Cincinnati Exhibition, but it has again been distinguished at Louisville by receiving the gold medal, which was the highest award offered by that exhibition.

The Lechner Manufacturing Company, Columbus, Ohio, has received orders for roller chain for driving purposes, from P. Andrews & Co., Cincinnati. The company has also furnished Jarvis Barnes & Co., Lansing, Mich., with one chain conveyor; the Columbus Elevator Company, with three elevators; and A. Bonnat & Son, Louisville, O., with two elevators.

Before Vice-Chancellor Van Fleet, at Newark, John H. Emery, counsel for Park Brothers & Co., of Pittsburg, lately appeared in behalf of an application for a decree to compel the Grant Locomotive Company, of Paterson, to render an accounting. When, some years ago, the Grant Company became embarrassed, in order to prevent its works from going into the hands of a receiver, it gave to Park Brothers & Co. and other creditors certain amounts of stock, agreeing to divide with these creditors the net profits of the company in liquidation of the debts, the stock to be surrendered when such indebtedness became canceled. Park Brothers & Co. assert that about $50,000 has been made by the company since this agreement, and that none of the net profits have been made over to them. Ex-Chancellor Williamson contended for the company that the apparent profits were not real, but appeared only as a matter of bookkeeping. The company, however, agreed to render the accounting, and the matter was postponed one week.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY.

The Florence *Enterprise* says that Messrs. White & Salsbury, of the Benson smelting-works, have bought the tailings of the Vulture mill—50,000 tons—carrying gold and lead. They will put up concentrators at the dump and ship the concentrations to their smelter at Benson. There will be sampling-works put up at Tucson soon by this firm, which is also putting in a new 50-ton galena furnace, and will also add a copper furnace soon.

COCHISE COUNTY—TOMBSTONE DISTRICT.

Work at the various mines continues as usual, and there is nothing of special interest to report. Great interest is manifested in the starting up of the powerful pumping machinery at the Contention, which, it is stated, will take place December 10th.

MARICOPA COUNTY.

NIAGARA.—A new arrastra has been put up at Cave Creek. The ore worked yields about $75 per ton. The shaft is now down some 29 feet, and a very rich pay-streak some six inches in width is exposed at that depth.

PIMA COUNTY.

The proposed smelter at Tuscon—reference to which we have made several times—will probably not be built. Mr. Aaron Mason, who was prominently connected with the scheme, has withdrawn. His action has caused a great flurry among the citizens of Tucson.

YAVAPAI COUNTY.

From Prescott comes the news that the city attorney has decided that the proposition to aid in the erection of a smelter by the city issuing bonds to the amount of $25,000, could not be legally complied with. The local press, speaking of ways of aiding the enterprise, says: Let our citizens agree to remit all taxation on plant and capital invested for a series of years, and in addition they can by subscription raise enough to purchase a good site and present it to any company which complies with the requirements.

CALIFORNIA.

INYO COUNTY.

SWANSEA.—The smelter is about completed, and was to blow in December 1st. The new furnace is one of Rankin & Brayton's best thirty-ton two-section water-jackets, with the new improvements and appliances. The new works are built about one mile east of the old Swansea works, and on the toll-road from Swansea to Cerro Gordo. The location is convenient, and elevated sufficiently to give plenty of fall for ore to the feeding or charging-floor, and also for a slag-dump. Water is furnished by the old well at Swansea, which gives a permanent and unfailing supply, and is forced up to the new works by a powerful steam-pump. The dumps at the furnace are crowded with smelting ores and rich slags from the old Swansea works. The company mines at Cerro Gordo are worked with encouraging results, and are producing ore in considerable quantities. The company is said to be financially sound, and the new works will start up without one dollar of indebtedness.

MONO COUNTY.

MAY LUNDY.—For some unknown reason, some seventy-five men were recently discharged.

BODIE DISTRICT.

BODIE CONSOLIDATED.—The recent reports show that the stopes have yielded only a fair quality of ore. It is, however, expected that better ground will be reached soon. An improvement has occurred at a point between the fifth and sixth levels, south. This portion is now opening, and in the course of two or three weeks it is believed ore will be sent from it which will grade the pulp higher again.

STANDARD CONSOLIDATED.—The usual progress is reported. The stopes throughout the mine continue to have the same good appearance.

PLUMAS COUNTY—GREENVILLE DISTRICT.

INDIAN VALLEY.—Work was stopped at the mine on account of the flow of water in the bottom of the shaft. The bottom of the shaft is now in much better ore than any before found in the mine, and the ledge is looking better than ever before. The quartz has changed from its tough, hard character higher up, and promises to be much easier worked.

SOUTHERN EUREKA.—The mill has probably started. From present appearances, a successful run is expected.

SIERRA COUNTY.

MARGUERITE.—Active work is going on at the mine in making preparation for running the hoisting-works by water-power. A wire cable capable of transmitting 300 horse-power will connect the water-wheel with the hoisting and pumping gear, the two being 1460 feet apart.

WISCONSIN EXTENSION.—In this gravel mine, softer rock has been encountered in the uprise started recently about twenty feet out from the face of the main tunnel. The Wisconsin tunnel has been run in a distance of 2200 feet, through hard rock, at a cost of $56,000. The entire work has been wholly of a prospective character.

COLORADO.

CLEAR CREEK COUNTY.

NEW YORK MINING AND MILLING COMPANY.—The mill, which is said to be one of the largest in the county, was erected to treat the ore from the Big Chief mine, a large quantity of which is now ready for milling.

GILPIN COUNTY.

FANNY.—The lessee is putting the main or discovery-shaft in working order.

HINSDALE COUNTY.

CROOKE MINING AND SMELTING COMPANY.—It is announced that all differences are settled, and that the English capitalists have paid up the arrearages and the deferred payments on the original purchase.

WHITE CROSS MINING AND MILLING COMPANY.—The Illinois Boy, the property of this company, is to be thoroughly developed. There are now over two feet of galena, which also carries 6½ per cent of copper, and a copper streak running 14 to 24 per cent; two and a half feet of clean shipping ore; and probably over five feet of concentrating ore.

LAKE COUNTY.

CATALPA.—Settlements just made for fifty tons of ore returned fifty dollars per ton. The output of the mine the past month will aggregate about $8000, and leave a profit to the company of probably $2500. Miners working the upper shaft on a lease reported having struck some ore in the eastern end of the claim, but the extent or value of the discovery is not yet known.

CARBONATE HILL.—The Yankee Doodle mine, the property of this company, is looking well and producing regularly. The earnings of the mine for the past month exceeded $5000.

CHRYSOLITE.—None of the company's dumps will be leased. The "Iron incline," driven in Chrysolite ground from the Colorado Chief shaft, has advanced to within 140 feet of the Roberts shaft. The face of the incline is in fine-looking iron ore.

COLONEL SELLERS.—This company has made a contract with the Boston & Colorado Smelting Company for five thousand tons of second-class ore, to be delivered within the next six months. A contract has also been made with the Arkansas Valley Smelting Company for four hundred tons of first-class ore a month. This, in addition to the contract of seven hundred and fifty tons a month with the Harrison works and odd lots shipped to other smelters in Leadville, Kansas City, and other points, enables the mine to make a fair showing again.

DUNKIN.—It has been decided by the new management to abandon the old working-shaft on this property, and hereafter work the mine through what is commonly known as the deep shaft. This shaft is provided with a commodious shaft-house and better hoisting machinery than at the old shaft. Some stringers of ore have been disclosed in the old mine.

HENRIETT.—The working force at this mine has been reduced.

HIGHLAND CHIEF.—The property was recently bought at trustee's sale by George Trimble for the bondholders.

IRON HILL CONSOLIDATED.—The shaft on the Imes lode owned by this company is nearly seven hundred feet in depth. A new hoist was recently put in this shaft, and work is now in progress at a depth of 435 feet, the line of contact between the limestone and porphyry. A fine streak of galena ore is reported to have been discovered.

MARIAN.—The Cyclops and other mines owned by this company, and bonded by Homer Pennock, are reported to have reverted to the company.

Digitized by Google

MIKE & STARR.—This company is still prosecuting work actively, notwithstanding the poor success that has attended exploration-work for many months past. The working force of the mine at present numbers about eighteen men, and the property is worked at an expense of about $2500 per month. Just now, a drift is extending to the southward, cutting through an immense body of pyritiferous ore, low in silver and lead.

NEW PITTSBURG CONSOLIDATED.—Work is pushed in a number of places. The Keene shaft, which had been idle for some time, is worked again. The shaft has a depth of 308 feet. A drift is now driving south from the lower level. The sinking of the new shaft, located a short distance north of the Keene shaft, is making good headway. The shaft was begun only a short time since and has already attained a depth of 120 feet. The bottom of the shaft is in porphyry, which it is expected to pierce daily. The Pierson shaft and contiguous workings are leased and also some other portions of the mine.

OPULENT & AUSTRALIAN.—The ore-body developed in these mines on the north side of Little Ellen Hill has developed an unusual size. As shown at present, the ore-chute has a width of forty-five feet and an average thickness of nearly thirty feet. The chute has been opened and worked for several hundred feet. The mineral extracted at present nets fifteen dollars per ton, and contains from one fourth to one and one half ounces in gold to the ton.

SILVER CORD.—Another reduction in the working of this mine has taken place. The force remaining now does not exceed twenty men, constituting the contractors who are advancing the main incline, engineers, and a few surface men. The construction of the ore-bins has also been suspended, as well as other surface work.

ST. BERNARD VS. BROOKLAND.—The suit brought by stockholders of the St. Bernard Mining Company, asking for an injunction prohibiting the consolidation of the St. Bernard and Brookland companies, has been decided by Judge Goddard in favor of the defendants. The consolidation will now be perfected without delay. A meeting of the stockholders of both companies will take place in a few days, and the organization of the Adams Mining Company, embracing both properties, completed. The sinking of the Clontarf shaft to greater depth has been commenced. The shaft is now down 515 feet, and by sinking it still deeper, it is thought that it will catch some of the water now flowing into the Brookland and Wolfe Tone shafts. If the flow of water can be equally divided between the three shafts, each of which is supplied with good Cornish pumps, no further trouble will be experienced in handling it. If successful, work will immediately be commenced in the Brookland shaft, where a large body of fine ore is now exposed.

OURAY COUNTY.

PANDORA & ORIENTAL.—This company has closed its mine and mill. It has been paying out on an average from $8000 to $10,000 per month. The strike of the miners is the indirect cause.

PARK COUNTY.

GRANITE.—This company sold to the Gem Mining Company, for 125,000 shares of the latter's stock, the Orphan Boy lode, in Hall Valley District. So the Leadville *Herald* reports.

SUMMIT COUNTY.

CLINTON CONSOLIDATED.—The property purchased for $60,000 by the syndicate composed of Philadelphia capitalists, headed by J. Whitaker Wright, comprises the Florence, Clinton, Cleopatra, and Prince claims. Regarding these mines, the Red Cliff *Shaft* says: The property is in good condition and most favorably located. Each claim is well opened up and all show mineral. The main incline on the Clinton is down 750 feet, the branch incline into the Cleopatra is down 650 feet. Besides these, the Cleopatra has an incline from the surface of 125 feet, which has exposed seams of handsome carbonates. The Prince is only a fraction of a claim thirty feet in width. It contains a distinct ore-body from the others, that will prove a bonanza when more thoroughly opened up. At present, only a small force is employed. A large working force is to be put on the first of December. The property is all to be operated from the Clinton incline, and is well equipped with a good engine and hoister and a comfortable shaft-house. The sale of the Clinton claim was mentioned in our last issue.

EL CAPITAN.—Some 700 pounds of ore from the mine were shipped to Philadelphia for treatment. The owners are endeavoring to find some process by which they can treat their ore with more success than has been done yet.

HORN-SILVER.—This mine, at Red Cliff, recently purchased by Joseph Chaffee and others, has made its first shipment of ore under the new management.

DAKOTA.

Local papers report that quite a number of strangers are arriving in the Harney District for the purpose of prospecting for tin. New locations are made every day, and the most flattering indications are met on every hand.

CALEDONIA.—According to the Black Hills *Pioneer*, work has been resumed in this mine by contract with Morris Jones and Frank Workman, each of whom is engaged running a 100-foot drift. The probabilities are, that the main shaft will be sunk 100 feet, and another station established. It is also rumored that the mill will be enlarged to twice its present capacity, or to 120 stamps. The mill will not, it is thought, start up before spring.

FATHER DE SMET.—Under date of November 15th, the superintendent writes: At the mine, work is going on steadily, showing very little changes. We have stopped work on east cross-cut, third level, and begun running south on the ledge instead. The face is now in four feet, all in ore, low grade in quality. Golden Gate chamber, second level, is opening well, and looks encouraging. The report for the week ended November 21st shows: Ore extracted from first level, 1000 tons; second level, 600 tons; third level, 350 tons. Ore milled, 1950 tons. Golden Gate south header, third level, advanced 5 feet. I herewith inclose you express company's receipt for bar No. 171, containing 722·53 gold, the result of run of mill for the first half of November. At the mine, work is advancing with the usual speed, showing no important changes taking place in any of the ore-breasts. Golden Gate chamber, second level, continues to look favorable, and is very promising. South header, third level, shows an improvement in the character of the ore, which is very important, this being the deepest point on the Golden Gate ledge. The mill is in fine condition.

GUSTIN BELT.—On account of the hardness of the rock, little progress is made in running the tunnel. Some high-grade ore is exposed, and the prospects are said to be flattering.

MINERVA.—At the stockholders' meeting, held in Deadwood recently, it was decided to begin work at once removing the Bogle mill and improving the tunnel. It is believed that the mill will be in operation within sixty days.

PORTLAND.—At this mill, the stamps will all be taken out and Blake crushers substituted. The new machinery will all be in position, ready to start up some time in February.

GEORGIA.

There is nothing of importance to report. Work at all the mines in Lumpkin County progresses well, and almost all the mills are in full operation.

IDAHO.

IMPERIAL.—The parties who recently purchased this claim for $2900 have recently sold fifty tons of ore that averaged $105 per ton. The shaft has attained a depth of 150 feet. Two levels and two tunnels have been run. A vein 10 feet wide of second-class ore carrying a streak of solid galena which varies from two to 20 inches in width is exposed. This galena is all that is extracted now. Next spring, jigs will be erected at the mine. Work will be continued all winter.

NARROW GAUGE-BANNACK.—During the past three months, these mines have produced about $125,000, most of which was from the concentrates of second-class ore which had accumulated on the dump before the jigs were put in.

PHILADELPHIA MINING AND SMELTING COMPANY.—It is stated that the ores reduced at the company's works this year averaged 149 ounces, and paid to the seller an average of $102 per ton.

KENTUCKY.

Attention is now attracted by the Kentucky oil-fields. This district lies on the boundary line of Kentucky and Tennessee. There are at present two shallow wells on a tract of 20,000 acres owned by a Mr. Marshall; and each of the wells has been producing three barrels each since 1873. R. P. Crawford, the well-known operator of Pittsburg, is said to have leased 30,000 acres adjoining the Marshall tract, for a Pittsburg syndicate, and the intention is to begin drilling at once. It is also said that a syndicate, with Michael Murphy and Mr. Whetmore, of Warren, at the head, has been formed to develop the Marshall tract. All the test-wells so far drilled in this district have only been put down to the first sand; but it is now the intention to drill to the fourth sand, if such there be in the district.

MAINE.

Three companies, composed of Auburn, Bath, and Newcastle capitalists, have been operating feldspar mines in Edgecomb. The Auburn Company, which was the pioneer in the industry, has taken out upward of 1200 tons of feldspar. The Bath Company, after having taken out some 200 tons, has suspended for the winter, but will start a much larger operation in the spring. The Newcastle Company, which is the latest organization, began operations the first of the present month, and took out forty tons in one week. The industry is yet in its infancy. Other valuable lodes have been discovered, and new companies will undoubtedly be started next season. The rock is loaded on vessels at a wharf two miles distant, and is shipped to Trenton, N. J., where it is manufactured into crockery ware. It sells for $6 per ton, giving an estimated profit of $2 a ton. It should be mined much cheaper, and will be when the mines are operated on a larger scale. Valuable quartz is also taken out with the feldspar, which is sold to sand-paper manufacturers in Malden, Mass. Merchantable mica is also found in considerable quantities.

DOUGLAS.—The leaching-works are in full operation, and during the present month 130 barrels of cement copper have been obtained from ore removed from the mine since the first of November. It is estimated that from this cement there will be obtained sixteen tons of refined copper as the monthly output.

MICHIGAN.

The Marquette *Mining Journal* estimates the output of the mines of the Marquette and Menominee districts at 2,300,000 gross tons, including ore shipped by rail and hauled to local furnaces. The last cargo of the season left Marquette recently.

DEXTER.—Operations will be resumed shortly, but will be confined principally to preparatory work during the winter.

LAKE SUPERIOR SLATE COMPANY.—This company has just been organized at l'Anse. Among the incorporators are the Messrs. E. T. and R. R. Williams, E. L. Mason, and E. H. Hayes. The capitalization is $1,000,000. The company owns 640 acres of valuable slate lands, located about one mile from l'Anse, and convenient to the Marquette, Houghton & Ontonagon Railroad. It is the purpose of the company to proceed at once with the work of development.

OLD ABE.—An assessment of two per cent has been levied upon the capital stock of the company.

PENN IRON COMPANY.—At both the Norway and East Vulcan mines, the working force will be increased. A new cage shaft just begun at the Norway will be sunk to a depth of 300 feet, and supplied with a large Cornish plunger-pump, which will raise the water from all the different pits. The shaft is located in the hanging-wall, about 200 feet north of the machine-shop.

MONTANA.

GALLATIN COUNTY.

Dispatches from Bozeman state that there is great excitement throughout Western Montana over rich mineral discoveries in the Cœur d'Alène Mountains. Prospectors who have returned state that no mines have ever been discovered in the history of the Western States and territories that equal the riches and volume of the newly discovered field. The minerals consist of silver, tellurium, and free-milling gold; $100 per day being taken out of the rim rock of gulches, while in the gulches from $25 to $40 per man per day are panned out. The streams are in the northern part of Idaho, near Eagle City, forty miles from Heron, on the Northern Pacific Railroad. There are now about 500 people in camp. The above reports are no doubt greatly exaggerated.

JEFFERSON COUNTY—BOULDER DISTRICT.

From this district, considerable activity in mining operations is reported. Two of the best-looking silver-lead mines are the Emma Bell and Adolphus, which have been bonded for $60,000.

LEWIS & CLARKE COUNTY.

BOSTON & MONTANA.—Work at the Gloster mine and mill will start up December 10th. The recent improvements made, it is stated, will enable the company to save at least 90 per cent of the value of the ore. It is proposed to run the mill 180 tons per day.

MISSOULA COUNTY.

BITTER ROOT SMELTER.—The first bar of bullion has been produced. This trial smelter has been recently erected, and works satisfactorily.

SILVER BOW COUNTY—SUMMIT VALLEY DISTRICT.

The prospects of all of the leading mines of the district continue to be good and all the mills and smelters are in full operation.

HARRIS TUNNEL.—Ever since the development of the rich copper-silver leads in the Anaconda and St. Lawrence mines, operations in the Harris tunnel, on the Johnstown, Little Idahoan, and Pennsylvania claims, which join the St. Lawrence on the east, have been regarded with great interest. The three claims are each full size, 1500 by 600 feet, extending east and west, the Pennsylvania lying south of the others, the Johnstown on the north side, and the Idahoan between the two. There is also a fraction 200 feet wide and the full length of the claim lying north of the Pennsylvania, which has been added to that property by purchase. The tunnel was started on the Pennsylvania ground 500 feet from the western line and 250 feet from the southern line of the claim, and has been run into the hill, trending a point east of north, a distance of 1142 feet. The country rock the entire distance is micaceous granite, and the ground is so solid that it has not been found necessary to use a stick of timber in the tunnel. A number of small veins have been cut through, all bearing the same characteristics of quartz carrying gray sulphurets of silver, with pockets of decomposed quartz mixed with carbonates. It is stated that the owners are in negotiation with a representative of London capitalists for its sale.

NEVADA.

The Virginia City *Chronicle* says that the Northern Belle Company will appeal from the recent verdict of $860,000 damages in favor of the Holmes Company. There are two points relied upon—first, that the U. S. Circuit Court did not have jurisdiction of the case; secondly, that the ground claimed by the Holmes Company, from which the ore was purloined by the Northern Belle, was government land.

ESMERALDA COUNTY.

MOUNT CORY.—In the suit of J. M. Brazell *against* J. C. Flood, G. R. Wells,

Digitized by Google

and others, a motion to dissolve a temporary injunction secured by the plaintiff has been granted. The action is brought to recover an eighth interest in the Mount Cory mine. The decision allows the defendants to proceed with their management of the mine without prejudice to the original action.

EUREKA COUNTY.

EUREKA TUNNEL.—Work has been resumed. This has been accomplished through an understanding with the judgment creditors.

NYE COUNTY.

BELMONT.—The company's mill is running by the leaching process entirely, which, it has been demonstrated, pays better than any other process for Belmont ores. The mine is reported to be prospecting well.

STOREY COUNTY—COMSTOCK LODE.

CALIFORNIA AND CONSOLIDATED VIRGINIA.—Senator John P. Jones has leased the upper levels from the California and Consolidated Virginia mining companies for a period of three years. He contracts to mine and mill all the ores that may be extracted from those mines above the 1550 level of the Consolidated Virginia, and to account to the company for 70 per cent in bullion of the assayed value of all such ores, and deliver to it all bullion extracted from said ore. All such bullion shall be sold at the earliest opportunity, and at going rates, and the proceeds derived from the sale shall be distributed to the payment of the Sutro Tunnel royalty, to the payment of 50 cents per ton to the company for all ore mined and milled, to expenses, to the payment of $9 per ton to Jones for milling and transporting such ores, and the balance to go to the company after the payment of all such sums. Senator Jones gives his bond for $10,000 for the faithful performance of the stipulations in the contract. This is said to be a favorable arrangement for the companies. The work in the lower levels will be prosecuted as usual.

HALE & NORCROSS.—In the north drift on the 2700, some fine ore, showing both chloride and black sulphurets and assaying high, is reported to have been found. The streak from which this assay was taken is about 15 inches in width, with a considerable width of black clay and low-grade quartz. The winze below the 2700 is now rapidly sinking. The water on the 2700 is not allowed to flow into the winze, but is caught up at the station.

OPHIR.—The old Morgan mill, formerly called Yellow Jacket, has been purchased by this company, and will run hereafter on Ophir ore from the upper levels. The price paid was $16,000. The mill is situated near Empire, on the Carson River.

NEW YORK.

RUSSELL.—The people of Ellenville are excited over this old gold mine situated at Fairtirskill. The existence of gold in the rock at that place has long been known, but the ore was not sufficiently rich to warrant reduction by any of the old processes. For some months past, however, an assayer of New York City has been experimenting with the ore. At a large public meeting, he stated that he believed the mine was the most extensive and valuable gold and silver deposit in the State. The ore seemed practically inexhaustible, and would yield by his process of reduction from $6 to $10 per ton. He thought that at a depth of fifty feet it would yield perhaps as high as $50 per ton. The assayer offered to take the mine and work it with New York capital, but Mr. Russell and the other owners prefer a home company, which will doubtless be organized at once. It is thought that the mine can be opened for work at a cost of $2000.

PENNSYLVANIA.

Mr. John Eyerman, of Easton, sends us the following notes: The corundum mine, near Shimersville, Lehigh County, has been working regularly since my last visit, an account of which was given in the JOURNAL of October 6th. About 15 shafts have been sunk, ranging in depth from 5 to 30 feet. A considerable quantity of corundum has been raised. Small quantities of menaccanite still accompany it. It is stated that five barrels were shipped to Philadelphia. An analysis by Mr. E. F. Smith gave: Al_2O_3, 85·75 per cent; SiO_2, 3·28 per cent; H_2O, 1·37 per cent; Fe_2O_3, 4·26 per cent: T_1O_2, 2·74 per cent; CaO, 1·99 per cent; MgO, trace. The specific gravity, also by the same person, was found to be 3·898. Several new shafts have been sunk about 300 yards from the old workings. On a former visit to the mines, and during the fair week at Allentown, I found all the mines idle, the men having gone to the fair.

The deposit of mica in Salisbury township, on Lehigh Mountain, has proved a failure. The lease is still held by Dr. Heller.

The brown hematite mines in Williams township, near Easton, have discontinued work, there being no demand for the ore. The Glen Iron Company's mines are still working.

A cave-in occurred a few weeks ago in an iron mine near Zionsville, Lehigh County, by which one man was killed.

As a matter of mineralogical interest, I may say that the finest specimens of botryoidal pyrite I have ever seen came from an iron mine near Shimersville, Lehigh County.

UTAH.

JUAB COUNTY.

BULLION BECK & CHAMPION.—The company is so well pleased with the progress of work that it contemplates the erection of smelting-works for the reduction of the ores. It has an iron mine within four miles of the property, which will be able to provide all the fluxing material that is required. There has been a strike of high-grade silver ore.

MILLARD COUNTY.

DESERET.—It is stated that this property is to change hands, the new owners being a wealthy firm of Detroit, Mich., and that it will pay up the old indebtedness. The E. P. H. mine should pay handsomely. The ore shipped to Chicago went 26·4 per cent copper, and after deducting $65 per ton expenses, netted about $20 per ton.

SUMMIT COUNTY.

APEX.—Thirty tons of low-grade ore were lately shipped to the Macintosh sampler. The ore went twenty ounces of silver and twenty-five per cent lead.

CRESCENT.—This mine will be worked all winter. The prospects are so favorable that the management has decided to increase the working force and to push the development of the mine.

ONTARIO.—The new developments in the west drift are very satisfactory. Three hundred men are employed, and the mine is reported to be in better condition than ever.

WISCONSIN.

Exploration for iron ore at Black River Falls will begin soon. The parties will use a diamond drill in the work. Considerable work of an exploratory nature was done by these gentlemen at the place in question during last year, and developments made that make a continuance of the work at this time warrantable.

PATENTS GRANTED BY THE UNITED STATES PATENT-OFFICE.

GRANTED NOVEMBER 6TH, 1883.

287,817. Process of Manufacturing Porous Siliceous Materials to be used as Fire-bricks, Filters, etc. Adolph Frank, Charlottenburg, Prussia, Germany.
287,831. Coal Elevator and Bucket. Albert L. Hitchcock, Pawtucket, R. I.
287,840. Ore-Concentrator. Hinche P. Mabry, Fort Worth, Tex.
287,842. Process of Manufacturing Bessemer Steel. Samuel McDonald, Braddock, Pa.
287,864. Open-Hearth Steel-Melting Furnace. Charles M. Ryder, Chester, Pa.
287,866. Portable Drill. William Sandiford, Joliet, Ill.
287,876. Crushing and Grinding Machine. George J. Shimer, Freemansburg, Assignor of one half to Samuel J. Shimer, Milton, Pa.
287,905. Coke-Oven. Francois Carvès, St. Etienne, France.
287,937. Utilization of Exhaust-Steam. Moritz Honigmann, Aix-la-Chapelle, Germany.
287,945. Ore-Reducing Furnace. George A. Lawrence, New York City, and Edward J. Frost, Philadelphia, Pa.
287,981. Process of and Apparatus for Amalgamating Ores. Charles E. Tripler, New York City.
287,986. Metal-Drilling Device. Palmer C. Wright, New Haven, Conn.
287,996. Molding-Machine for Foundry Use. Frank Bardez, San Francisco, Cal.
288,0f0. Pulverizing-Machine. Ryerson D. Gates, Chicago, Ill.
288,079. Steam-Boiler Furnace. Fountain Livet, London, England.
288,176. Roll for Rolling Metal. William E. Harris, St. Louis, Mo., and Edwin B. Evans, Covington, Ky., Assignors of one fourth to Samuel Knight and George H. Knight, both of St. Louis, Mo., and Octavius Knight, Washington, D. C.

REISSUE.

10,400. Process of Roasting and Disintegrating Gold and Silver Ores. David W. Birmingham, Clifton, N. Y.

GRANTED NOVEMBER 13TH.

288,337. Brick-Machine. James Hodkinson and Franklin P. Miller, Chambersburg, Pa.
288,347. Brick-Kiln. Henry Konhorst, Henderson, Ky.
288,359. Wire-Stretching Machine. Daniel W. Norris, Elgin, Ill., and Wesley Young, Dayton, Ohio; said Norris Assignor to said Young.
288,403. Boring-Machine. Hibbard T. Bowen, Philadelphia, Pa., Assignor of one half to Philemon P. Bowles, same place.
288,416. Furnace. Thomas M. Fell, Brooklyn, N. Y.
288,418. Furnace for Steam-Boilers, etc. William C. Ford, Brooklyn, N. Y.
288,421. Nailing-Machine. Louis Goddu, Winchester, Mass., Assignor to Gordon McKay, Newport, R. I., and James W Brooks, Cambridge, Mass., Trustees.
288,422. Nailing-Machine. Louis Goddu, Winchester, Mass., Assignor to Gordon McKay, Newport, R. I., and James W. Brooks, Cambridge, Mass., Trustees.
288,423. Nailing-Machine. Louis Goddu, Winchester, Mass., Assignor to Gordon McKay, Newport, R. I., and James W. Brooks, Cambridge, Mass., Trustees.
288,424. Nailing-Machine. Louis Goddu, Winchester, Mass., Assignor to Gordon McKay, Newport, R. I., and James W. Brooks, Cambridge, Mass., Trustees.
288,425. Nailing-Machine. Louis Goddu, Winchester, Mass., Assignor to Gordon McKay, Newport, R. I., and James W. Brooks, Cambridge, Mass., Trustees.
288,435. Air-Compressing Engine. Friedrich Honigmann, Aachen, Germany.
288,436. Steam-Pump Regulator. William D. Hooker, St. Louis, Mo.
288,437. Air-Supplying Device for Steam-Boiler Furnaces. James Bowden, Glasgow, County of Lanark, Scotland.
288,445. Gas-Burner for Heating and Metallurgical Purposes. James E. Karns, Apollo, Pa.
288,466. Kiln for Burning Brick, Tiles, etc. Henry McCue, St. Louis, Mo.
288,477. Hydrocarbon-Furnace. Orland D. Orvis, Chicago, Ill.
288,484. Seal for Miners' Squibs. John R. Powell, Plymouth, Pa.
288,501. Rolling-Mill. Thomas Shaffer, Phœnixville, Pa., Assignor to the Phœnix Iron Company, same place.
288,505. Fuel-Feeding Device. George Sinclair, Leith, County of Mid-Lothian, Scotland.
288,510. Drilling-Machine. George C. Taft, Worcester, Mass.
288,520. Gold-Separator. Hiram C. Walker and William Bacon, Silver Cliff, Colo.
288,550 Ore-Separator. Joseph A Coombs, New York City, Assignor of one half to John Henderson, Baltimore, Md.
288,554. Smoke-Consuming Furnace. George W. Davisson, St. Louis, Mo.
288,574. Drier for White Lead and other Materials. George L. Irwin, Alleghany, Pa., Assignor to himself and R. L. Orr, same place.
288,575. Sheet-Metal Machine. Whitfield E. Jones, Brooklyn, N. Y.
288,607. Blast-Furnace for Burning Gaseous Fuel. Levi D. York, Portsmouth, Ohio.

GRANTED NOVEMBER 20TH.

288,622. Carburetor. Charles F. Copeland, Boston, Mass., Assignor to the Thermo Gas Carbonizer Company, of Maine.
288,632. Gas-Engine. Wilhelm Hammerschmidt, Philadelphia, Pa.
288,638. Tool for Facing Emery-Wheels. Joseph D. Huntington, Chicago, Ill.
288,649. Brick-Machine. Gaylord Martin, Milwaukee, Wis., Assignor of two thirds to Thomas C. Gurney, same place.
288,677. Wire-Rope Machine. Thomas S. Stevenson, St. Louis, Mo.
288,701. Process of and Apparatus for Making Heating and Illuminating Gas. Thomas M. Fell, Brooklyn, N. Y.
288,706. Blasting-Tool. Henry Iwan and Lewis Iwan, Streator, Ill.
288,716. Process of Manufacturing Charcoal. Jean A. Mathieu, Philadelphia, Pa.
288,724. Attrition-Mill. John J. Newsom, Oakland, Assignor of one half to James C. Plunkett, San Francisco, Cal.
288,741. Apparatus for the Manufacture of Gas. Roland H. Smith, Pittsburg, Pa.
288,745. Ore-Pulverizing Mill. William I. Tustin, San Francisco, Cal.
288,750. Roller-Mill. Abraham N. Wolf, Allentown, Pa., Assignor of one half to Winslow Wood, same place.
288,752. Gas-Machine. Joseph S. Wood, Brooklyn, N. Y.
288,760. Dumping-Car. Andrew Beckert and William E. Ludlow, Sandusky, Ohio.
288,761. Coke-Oven Door. William H. Beckwith, Latrobe, Pa.
288,813. Dumping-Wagon. Robert Hudson, Gildersome, County of York, England.
288,827. Compound Metal-Working Machine. Gilbert McDonald, Georgetown, New Mexico, Assignor to himself and James A. Lucas, same place.
288,840. Steam-Hammer. Frederick B. Miles, Philadelphia, Pa.
288,844. Middlings-Purifier. Theodore H. Neander, Wataga, Ill.
288,868. Carburetor. John H. Saunderson, Trenton, N. J.
288,874. Coke-Oven. Georges Seibel, Cransac, France.
288,877. Gas-Producer. Charles W. Siemens, Westminster, County of Middlesex, England.
278,878. Gas-Producer and Furnace Operating in Connection therewith. Charles W. Siemens, Westminster, County of Middlesex, England.
288,882. Ratchet-Drill. Albert Söderström, Stockholm, Sweden.
288,894. Brick and Tile-Machine. William W. Wallace, Frankfort, Ind.
288,895. Clay-Crusher. William W. Wallace, Frankfort, Ind.
288,936. Machine for Bending Metal. Thomas Rice Freeman, Sioux Falls, Dak., Assignor to himself and James Bradley Vandaworker, same place.
288,940. Crushing and Pulverizing Apparatus. Amos E. Griffiths, Philadelphia, Pa.
288,952. Combined Gas-Engine and Carbureting Apparatus. Henry L. Muller, Birmingham, England.
288,957, Self-Oiling Drill-Chuck. Albert Söderström, Stockholm, Sweden.

GRANTED NOVEMBER 27TH.

288,979. Compound for the Manufacture of Steel. Edward Coyle, St. Louis, Mo.
289,018. Ore Concentrator. Jonathan Miller, Concord, N. H.
289,024. Brick-Kiln. James W. Penfield, Willoughby, Ohio.
289,064. Apparatus for Extracting the Precious Metals by Means of the Lead Bath. William Walton Brown and Lewis Adelbert Gates, San Francisco, Cal.
289,085. Process of Purifying Molten Iron. William Griffith, Pittsburg, Pa., Assignor to himself and James C. Gray, same place.
289,086. Process of Purifying Molten Iron. William Griffith, Pittsburg, Pa., Assignor to himself and James C. Gray, same place.
289,087. Process of Purifying Molten Iron. William Griffith, Pittsburg, Pa., Assignor to himself and James C. Gray, same place.
289,088. Process of Purifying Molten Iron. William Griffith, Pittsburg, Pa., Assignor to himself and James C. Gray, same place.
289,089. Process of Purifying Molten Iron. William Griffith, Pittsburg, Pa., Assignor to himself and James C. Gray, same place.
289,110. Hand Drilling-Machine. Daniel E. Kempster, Boston, Mass., Assignor to George W. Smith, same place, and Benjamin F. Smith, Somerville, Mass.
289,143. Cupelling-Furnace. Bernhard Roesing, Friedrichshütte, Upper Silesia, Germany.
289,152. Ore-Concentrator. Peter A Simmons and Charles J. Henry, Leadville, Colo.
289,201. Gas-Burning Puddling-Furnace. Joseph C. Williams, Etna, Pa.
289,231. Mine-Shaft Elevator, Michael F. Coleman, New York City.
289,261. Ore-Separator. Benjamin Hershey, Erie, Pa.
289,293. Apparatus for Concentrating Sulphuric Acid, Samuel T. McDougall, Brooklyn, N. Y.
289,300. Rock-Drill. John Naylor and Robert Thornton, Stawell, Victoria.
289,343. Smoke-Consuming Furnace. Patrick W. Frain, St. Louis, Mo.
289,354. Apparatus for Feeding Fuel to Furnaces. James McMillan and William A. Robertson, Glasgow, County of Lanark, Scotland.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Dec. 7.

Business in the mining market this week was mostly confined to a few stocks, and outside of these there was but little of interest. The principal feature in the market was the weakness of Northern Belle. The sharp decline in this stock, as we stated last week, was owing to a large judgment having been rendered against the company. The production of the mine for the last half of November is said to be $25,000; and, if this is the case, the judgment obtained should not affect the price of this stock to the extent it has. Another feature of the market was the sharp decline in Iron Silver. It is said that, owing to the low price of lead, the production of this mine is not so large now as it has been recently. The dealings in Eastern Oregon and Sonora Consolidated continue to be very large, but no material change in price is recorded. The general character of the market, with but few exceptions, was weak and unsettled, and it may be said to have closed in that condition to-day. The total number of shares sold aggregates 110,538, as against 106,617 last week.

The Comstock shares were generally weak and were but moderately dealt in. California was quiet and weak, selling from 20@22@12c. Consolidated Virginia was weak under a small business, selling from 34@29@31c. Sierra Nevada was also weak; it sold from $2.65@$2.45 with small transactions. Union Consolidated was quiet and steady at $2.20@$2.55. Savage was very weak, selling from $3.50@85c. assessment unpaid; the sales amounted to 500 shares. Sutro Tunnel was quiet and steady at 16c.@15c.

The Leadville stocks were quiet at steady prices. Amie sold at 11c. under a small business. Chrysolite was moderately dealt in and was strong; it sold from $1.30@$1.40. Dunkin was steady, selling from 25@27@26c. Iron Silver was very active and was quite weak; it sold from $2.25@$1.80. An officer of this company stated that the decline in this stock was owing to the weakness of the lead market. Leadville was quiet and steady at 47@46c. Little Chief was fairly dealt in at steady prices; it sold from 54@59@58c. Little Pittsburg, under a small business, sold at 51c. Climax was quiet and steady at 7@6c.

The Bodie stocks were quiet at weak prices. Bodie was quiet and weak, selling from 90@70c. Standard was a little weak, selling from $7@$6; the latter price is ex dividend of fifty cents, under a fair business. Bulwer was very quiet at 48c.

The Tuscarora stocks sold at weak prices under a very small business. Grand Prize sold from 30@25c. Belle Isle was quiet and weak, selling from 30@20c. Independence sold from 6@4c., with small transactions. Elko Consolidated was quiet and steady, selling from 17@18c.

In the miscellaneous list, Eureka Consolidated was quiet and steady at $3.50. Father de Smet was also steady under a small business, selling from $2.50@$2.25. Gold Stripe was very quiet at 9c. Green Mountain sold at $1.20. Homestake was quite strong, under a small business, selling from $10.50@$11.50. Horn-Silver was irregular under a moderate business, selling from $7@$6.25@$6.75. Northern Belle was very weak, selling from $1.75@95c.; the stock was moderately dealt in. Robinson Consolidated was quiet and weak, selling from 32@29c. Sierra Grande was quite weak, under a small business, selling from 72@62@68c. Silver King was strong at $7.50. Castle Creek was quiet and steady, selling at $1.

Barcelona was quiet and weak, declining from 27@24c. Bradshaw sold at 16@15c. under a small business. Central Arizona was quiet and steady, selling from 24@22c. Decatur records but one transaction at 4c. Eastern Oregon was very active at steady prices; it sold from 44@46@45c. Harlem was strong, with a fair business, selling from $1.05@$1.15. Lacrosse sold at 8c., and was quiet. Sonora Consolidated was very active at steady prices; it sold from 27@25c.

A special meeting of the stockholders of the Hibernia Silver Mining Company was held at No. 46 Exchange place, this city, on Saturday last, to vote upon the question as to whether the recent contributions, made for the purpose of recovering the property, should be returned or not. There seemed to be but one opinion expressed at the meeting, and that was against returning the contributions, the sense of the meeting being that, on the contrary, it would be better to continue to push suit against the parties now holding the property. The president stated that the present board of directors had done every thing they possibly could to benefit the company and recover the property, but that, owing to the unfortunate state of affairs, caused greatly by their inefficient counsel at Leadville, up to the time of the meeting, had succeeded in making very little progress toward the recovery of the property. The contribution of the stockholders was safe, however, and the interest on it had, by economical management, defrayed all expenses.

The general feeling among those present was, that it was best to continue the fight, and a stockholders' committee of three was appointed to draw up a circular giving a statement of the condition of affairs, and soliciting the individual expression of the stockholders.

DIVIDENDS.

The Leadville Consolidated Mining Company, of Colorado, has declared a dividend (No. 9) of $20,000, payable December 20th.

The Mount Diablo Mining and Milling Company, of Nevada, has declared a dividend (No. 4) of twenty-five cents per share, payable November 26th.

The Plymouth Consolidated Gold Mining Company, of California, has declared a dividend (No. 7) of $50,000, payable immediately.

The Standard Consolidated Mining Company, of California, has declared its usual monthly dividend of twenty-five cents per share, also an extra dividend of twenty-five cents per share, both payable December 12th, at the Farmers' Loan and Trust Company.

DIVIDENDS PAID FROM JANUARY 1ST, 1883.

NAME OF COMPANY.	Location of mines.	Paid during month of November.	Since January 1, 1883.

MEETINGS.

The St. Joseph Lead Company, No. 152 Broadway, New York City. The special meeting of the stockholders of this company for the purpose of increasing the capital stock from $1,000,000 to $1,100,000, which was to have been held on December 4th, has been postponed to December 18th, at one o'clock P.M.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway, New York, report as follows on the market for the past week:

Last Friday, the highest market price was $1.17⅝. Saturday, the highest was $1.17. Monday, the highest was $1.17. Tuesday, the highest was $1.16⅞. Wednesday, the highest was $1.15⅝. Thursday, the highest was $1.14½.

Thus it will be seen that each day the market lost ground, and it appeared that large holders who had greatly influenced the sharp advance from $1.10 to $1.20 had marketed a large part of their holdings, and were willing to see lower quotations, if not to help the market to a lower range of prices.

There was no adverse news from the field, and the only bear points, outside of speculative considerations, were based on the theory that the refined oil market was not in a healthy condition, and that the shipments from the oil regions were likely to grow smaller as the winter advanced.

The trade in petroleum is now so extended that it takes some time to hear from the different markets, to determine what the drift of sentiment is as to the market. There is probably, however, a general feeling that during this winter higher prices will be attained both for crude and refined.

Both of the New York Petroleum Exchanges have appointed committees to confer on the question of consolidation, and the prospect is fair that the best sentiment of both Exchanges will favor a union of the two.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

		Opening.	Highest.	Lowest.	Closing.	Sales.
Dec.	1	$1.16⅛	$1.17	$1.16	$1.16⅝	4,138,000
	3	1.16⅛	1.17	1.16⅛	1.16⅛	3,139,000
	4	1.16¼	1.16⅞	1.15⅝	1.15⅝	2,558,000
	5	1.15¼	1.15⅝	1.13½	1.13⅝	7,894,000
	6	1.13¼	1.14⅛	1.13⅜	1.13⅞	7,480,000
	7	1.14¼	1.15¾	1.14⅛	1.15⅝	6,231,000
Total sales.						33,440,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, December 6.

The market for mining stocks continues to rule extremely dull and inactive, although for Calumet & Hecla there has been a fair demand and all the stock

Digitized by Google

offered for sale has been taken at $239@$240. There has also been a little more demand for Franklin at $11⅛@$11¼, on the report that a dividend will be declared next month. Outside of these two stocks, there have not been sales of over fifty shares all told. One share of Quincy sold at $52 ; five shares of Osceola at $18⅛ ; five shares of Pewabic at $3⅛ ; three shares of Atlantic at $9; and 35 shares of Huron at 50@62½c. All the transactions at the Board would hardly give a broker a fair day's work. How long this condition of things is to last, is a conundrum which we brokers should like to have answered. The reports from the mines generally continue favorable. The November product of the Franklin was 200 tons, against 180½ tons last year. The Huron has called for an assessment of $1 per share, for the purpose of furnishing another set of stamps. The product for November was 73 tons. The Pewabic shows a falling off to 45 tons as compared with 71 tons last year.

In silver stocks, Silver Islet sold at $3. Catalpa declined to 35c. ; Bowman Silver, to 13c. Massachusetts & New Mexico was freely offered at 3c. Dunkin 27c. bid, without sales. Sullivan, steady from 87½@92c. State street gossip says the Sullivan mine is taking out some remarkably rich ore for a Maine property. The estimated assay is $2000 per ton. How much ore there is of this grade is not stated.

3 P.M.—At the afternoon Board, Franklin sold at $12 ; Pewabic, at $3 ; Sullivan, at 90c. ; San Pedro, at 15c. ; Catalpa, at 35c.

BULLION MARKET.

NEW YORK, Friday Evening, Dec. 7.

There has been some advance abroad in rates of exchange on India, with a corresponding rise in silver, but the immediate future of the market may be regarded as uncertain.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended December 7th, as compiled from various sources, amounted to $288,000, as against $214,000 reported for the previous week. The receipts from January 1st, 1883, to date are $10,818,448.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended December 1st	$338,500
Corresponding week last year	133,148
Since January 1st, 1883	13,704,718
Corresponding period last year	45,170,450

Imports.

Week ended December 1st	$261,484
Corresponding week last year	428,680
Since January 1st, 1883	19,720,565
Corresponding period last year	6,237,549

United States Assay-Office at New York.—Statement of business for the month ended November 30th, 1883 :

Deposits of gold :		
Foreign coin	$1,492,600	
Foreign bullion	1,956,700	
United States bullion	499,700	
United States bullion (re-deposits)	243,500	
Jewelers' bars	92,500	
Refined gold	130,000	$4,415,000
Deposits of silver :		
Jewelers' bars	20,000	
Foreign coin	7,500	
Foreign bullion	16,500	
United States bullion (contained in gold)	9,200	
United States bullion (re-deposits)	1,800	
United States bullion, Arizona	3,800	
Colorado	24,000	
Dakota	17,800	
Idaho	11,600	
Lake Superior	5,100	
Montana	246,000	
New Mexico	16,700	
Utah	96,000	
Refined silver	137,000	613,000
Total deposits		$5,028,000
Gold bars stamped	$3,787,238	
Silver bars stamped	469,216	$4,256,455

United States Mints.—At the mint in Philadelphia, during November, 8,129,000 pieces, valued at $1,972,410, were coined.

The Treasury Department has purchased 300,000 ounces of fine silver for the Philadelphia and New Orleans mints.

Foreign Bank Statement.—The governors of the Bank of England, at their regular weekly meeting made no change in the bank's minimum rate for discount, and it remains at 3 per cent. During the week, the bank lost £152,000 bullion, and the proportion of its reserve to its liabilities was reduced from 43 3/16 to 42¼ per cent, against 40 5/16 per cent at this date last year. The weekly statement of the Bank of France shows a gain of 4,425,000 francs gold and a loss of 1,525,000 francs silver.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible ; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy ; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14½ per cent, to arrive at actual value.

MINES.	States.	Month of October.	Year from Jan. 1st, 1883.

METALS.

NEW YORK, Friday Evening, Dec. 7.

Copper.—Under a light business, the market has remained practically stationary. A number of small lots of Lake copper have changed hands at 14⅞c., which is now the nominal quotation. Baltimore has been selling at 14½c., while certain Arizona brands bring as much as 14⅝@14¾c. The situation of the metal is statistically a favorable one, and it needs apparently nothing but a revival in the demand and an improved tone of the markets abroad to strike higher values. The advices by cable from England are not, however, encouraging, Best Selected being quoted £65 and Chili Bars £59@£59 2s 6d.

Tin.—The market has been quiet and dull, with transactions at 19@19½c. for Straits, cash. Yesterday, 275 tons arrived. The feeling is one of ease. London cables £85 12s. 6d.@£85 17s. 6d.

Lead.—On Tuesday, 400 tons of Pueblo lead were sold at 3·60c. ; and since then second hands have been flooding the market with offers at that figure, the impression being created that the holders of other brands like Aurora and Horn-Silver are available at the same figure, while in reality they are understood to be held at 3·20c. However, the future may develop, and in spite of the fact that the elements of dullness continue, and that there is no anxiety to buy whatever, large lots could not be readily obtained at 3·60c. This should be stated because the opinion appears to have gained ground that all the producers had lost faith in the future of the metal, while, in fact, a number of them show a disposition to bide better times.

From St. Louis, Messrs. John Wahl & Co. wire us as follows to-day :

Our market is dull, the demand being only moderate. Sales will not foot up to more than 90 tons of Common at 3·37½c. and 130 tons of Refined at 3·40c.

Messrs. Everett & Post telegraph from Chicago :

There has been an increased demand for spot lead during the past few days. Sales during the week foot up to 1000 tons at 3·32@3·35c.

Spelter.—The situation is unchanged. We quote 4⅝@4½c. for Common Domestic. England quotes by cable £15 7s. 6d.

Antimony.—There has been no change whatever.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Dec. 7

Mr. Edward J. Shriver, Secretary of the Metal Exchange, has published the following returns :

Eighty-four furnaces, all kinds : 36 in blast, 48 out of blast.

	Stocks. Nov. 1.	Dec. 1.
All grades.		
Anthracite	16,295	11,568
Bituminous	16,687	16,371
Charcoal	11,495	11,801
Grand total	44,477	39,740
	Production. In Oct.	In Nov.
Anthracite	9,788	10,406
bituminous	20,993	33,386
Charcoal	2,227	2,260
Total	33,008	36,052

American Pig.—The market does not reveal any activity, but, on the other hand, shows no signs of weakness, holders having numerous inquiries for small lots, maintaining prices fairly well. With the close of the year at hand, there is, of course, no buying to cover any thing but immediate wants. We continue to quote $20@$20.50 for No. 1; $18.50@$19 50 for No. 2 ; and $17@$19 for Gray Forge at tide-water. Bessemer Pig is dull at $20 nominally, while Spiegel is lower, offers not going higher than $29 for 20 per cent.

At the Exchange, the following transactions were recorded during the week : Monday, 100 tons American Pig, No. 1, March, $20.12½ ; 200 do., $20.26 ; 100 do., April, $20.37½. Wednesday, 100 tons American Pig, No. 1, April, $20.50. Thursday, 100 tons, No. 1, April, $20.25.

Scotch Pig.—The market is very dull and quiet, transactions being limited to small lots.

We quote ex ship and to arrive : Coltness, $22.50@$23 ; Langloan, $2.75@$23 ; Summerlee, $22.50; Eglinton, $20@$21 ; Glengarnock, $21.75@$22 ; Dalmellington, $20@$21.

At the Exchange, the following cable quotations were received to-day : Coltness, 54s. 9d.; Langloan, 53s. 6d.; Summerlee, 53s.; Gartsherrie, 51s. 6d.; Glengarnock, at Ardrossan, 52s. 3d.; and Eglinton, at Ardrossan, 46s. Warrants at the Exchange to-day were 44s. 5d.

Steel Rails.—Is is said, though the statement is accepted with reserve, that the late unpleasantness at Chicago which led to the sale of rails at $32.25 at mill, as reported last week, is over. It is given out that the Pennsylvania Railroad has placed orders for 50,000 tons, with the understanding that the price be governed by the market price at time of delivery. Nominally, rails are now $35 at mill, and $35.50 for small lots.

Old Rails.—A few round lots of Tees have been placed. We quote $22@$22.50.

Philadelphia. *December 7*

Pig-Iron.—It is unsafe, at this time, to indulge in predictions as to the future of the market The

regulation cant at present is, that the holiday season is approaching, and business is, for this reason, dropping off; but such is not the case. During the past few days, some large sales of pig iron have been made, and others are likely to be made before the close of the year; but transactions depend upon the acceptance of offers now in hand, which are for irons not regarded as strictly standard. The reason for this activity, if it be possible to assign one, is, that consumers look for an improving demand after the close this month, and if they can buy on their own terms at present, they are willing to do so. The reason for the preference for inferior irons is, that the standard makes are held a little higher than consumers are prepared to go, or rather, the difference between standard and inferior is such as to induce buyers to prefer the latter; nevertheless, the market may be characterized as quiet and steady, but it is in better shape than was expected a week or ten days ago. Some makers are selling quite freely, others are not. The absence of large stocks in consumers' hands is a favorable fact which will go to help the market now and next month. Average quotations this week for No. 1 Foundry, $20@$21, a few hundred tons have sold at $21½@$22, for special makes of iron not easy to get. Makers of special brands report their furnaces pretty well sold up, and those who are not are not rushing stocks upon the market. The increase in production is not such as to make any further decline in prices probable. On the whole, there is a better feeling in the market, and the probabilities are strongly in favor of a moderate improvement in demand. After the first of the year, it is probable that consumers will find it advisable to carry larger stocks. All kinds of iron show a slight increase in production in November over October. Stocks of unsold iron are slightly less, which is another favorable point. The supply of No. 2 is still in excess of demand, and is the weakest of the three kinds. Gray Forge is selling in small lots, as manufacturers are still afraid to buy largely. Some mills will close down next week, and it is impossible to say when they will resume production. Manufacturers will be guided by the market, but there is no disposition to rush stocks off at the present low prices.

Muck Bars.—A few hundred tons were asked for this week at $33, but actual transactions were small.

Blooms.—There has been a moderate movement of Charcoal at $57, and Anthracite at $47.

Merchant Iron.—The fact that prices for bar iron have declined to the lowest possible limits, associated with the fact that several mills will suspend production from three to four weeks, has had the effect of inducing consumers to make inquiries for large lots for early delivery. There is more disposition to buy just now than last week, because of these reasons, and also because of the possibility of a rush into market by a good many large buyers soon after the 1st of January. Still, the prices taken for large orders this week show no improving tendency, some being as low as 1·80c., and very few over 2c. Between these limits, almost all business is likely to be done. Sales of 1000 tons of Skelp iron have been reported, and there are inquiries for from 1000 to 1200 tons more, which will probably be placed within a short time.

Nails.—Since the ordering of the five-weeks' suspension in all Western nail mills, there has been a growing dissatisfaction among the manufacturers, one after the other refusing to carry out the agreement, believing it to be ill advised and not to the best interest of the trade. On the 5th of this month, an animated meeting of the Western Association was held in Pittsburg, and, after much discussion, the order was revoked, it being decided that, except for the usual holiday suspension, the mills would all work as usual. Jobbing demand is rather light; very few car-load lots are selling; ordinary quotations, $2.80@$2.90, but sales have been made at less.

Plate and Tank Iron.—Nothing outside of a few small orders can be reported this week, although makers claim that large sales are probable next month. To-day's quotations are: 2·35c. for Boat Plate; 2·40@2·50c. for Tank; 3@3·25c. for Shell; 4@$4·25c. for Flange; and 5@5·25c. for Fire-Box.

Structural Iron.—A feeling of hopefulness is shown among the brokers who place most of the business for structural iron, and it is known that there are several large orders likely to be placed for bridge iron in January; but for the past week or two, business has been of trifling dimensions. Quotations are given as usual, at 2·40c. for Angles, 2·75@3c. for Tees, and 3·50c. for Beams and Channels.

Wrought Pipes and Tubes.—Quotations for to-day, 70 and 10 to 75 per cent off for Gas and Steam Pipe, and 60@62½ off for Boiler Tubes.

Sheet-Irons.—Mills are doing a small business. Thin sheets are in the best demand. Galvanized is selling at 45@55 per cent off list.

Steel Rails.—The recent heavy sales of steel rails in the West have been followed by a quietness in Eastern mills which is not likely to be disturbed until after the opening of the year. The Edgar Thomson Works are completing facilities for production which will enable them to reduce the price of rails from $2 to $3 per ton. Other mills will not permit this mill to excel them, and the same improvements will probably be introduced in all other works as soon as practicable.

Pittsburg. December 7.

In the absence of any actual improvement in the iron trade, makers and brokers are manufacturing one, which is shown in the expression of increased confidence in an early improvement in demand and prices. A few large transactions took place this week. Bessemer pig sold in 1000-ton lots at $20.50; Gray Forge iron, $17.50@$18.50, according to quality. Very little Foundry is moving at any price. Mottled iron, $16.50@$16.75. Charcoal Foundry, $23@$25 Average price for good Gray Forge Iron, $18. Some little mill iron has sold at $17@$17.50. Muck Bar is extremely dull, and makers are offering stocks at $32; but no bids are received over $31.50, and a number have been made at $31. As to manufactured iron, some makers are selling large quantities and report business active, while others report business dull and sales limited. It is impossible to give an exact account, as manufacturers give such contradictory reports. Quotations 1·80@1·90c., but sales have been made at 1·70c. and, it is said, at less. Nails are quoted at $2.50@$2.65, with sales said to have taken place at $2.40@$2.45. Wrought Pipes and Tubes, 70@75 off for pipes and 65 for tubes. Old Rails are quoted at $23 50@$24.50. Large blocks are wanted next year, and buyers name $23@$23.50. Scrap-Iron, $21@$22.50 for No. 1 Wrought. Car-Axles, $30. Cast brings $19.

COAL TRADE REVIEW.

Anthracite.

NEW YORK, Friday Evening, Dec. 7.

To-day, the announcement was made that there would be a stoppage, if necessary, of anthracite on December 13th, 14th, 15th, 20th, 21st, 22d, 24th, 25th, and 26th. This is simply recognizing the fact that there is an excess of production, without meeting the evil. It will be noticed that, even during the holiday week, the days are so chosen that there will be a maximum of production, instead of simply stopping for the entire week. We echo the sentiments of the entire trade when we say that the action taken is not at all likely to produce the effect it ostensibly aims at creating. By the close of navigation, the market was confined to tide-water points, and it is beyond all doubt that, with production going on at the rate contemplated, it will be flooded. Prices can not stand such a strain, and must weaken, so that the coal companies are needlessly imposing upon themselves the great and thankless task, for the future, of carrying them upward. As it is now, good stove coal is obtainable at $4 per ton, and, should the present unfavorable state of the weather continue, may reach a lower level. Buyers naturally show no anxiety for the future.

Coal has endeavored, in collecting the following figures, to arrive at some indications:

	Week ended Jan. 13 (Full-time).	Jan. 20 (Half-time).	Feb. 3 (Half-time).	Feb. 10 (Full-time).

Phila. & Reading	121,740	109,681	207,966	125,276

These figures do not, so far as we are able to discover it, reveal any law that might be used in guiding the trade to appreciate the effect of three-day stoppages. The figures for the Delaware & Hudson Company show some irregularity, but on the whole reveal a percentage little higher than one half product, though some weeks show that a little pressure will apparently run up the shipments. The Delaware, Lackawanna & Western appears to do, as a rule, considerably more than its share, its three-days' work footing up pretty closely to 5 per cent of its half-time shipments. This fully accords with its anxiety to see "restriction" carried out in this particular way. The Lehigh Valley is exceedingly irregular, and the same may be said of the Central Railroad of New Jersey, both appearing to be capable of forcing shipments. The Philadelphia & Reading Company sends but little more than one half of full-week product, in times of three-day stoppage.

Bituminous.

Harbor freights are easier, and freights from shipping points lower. Business is still dull, with the possible exception of the steamer trade, which takes a little more fuel. Prices are still low and irregular.

Buffalo.

The following statement shows the ruling rates of freight on coal per ton from Buffalo to Chicago and Milwaukee during the season of 1883, at the dates specified:

1883.	Per ton.
April 20	60 cents.
May 5	50 "
" 12	50 "
" 19	75 "
" 26	75 "
June 2	75 "
" 9	75 "
" 16	75 "
" 23	75 "
" 30	60 "
July 7	50 "
" 14	50 "
" 21	50 "
" 28	50 "
Aug. 4	70 "
" 11	70 "

1883.	Per ton.
Aug. 18	70 cents.
" 25	70 "
Sept. 1	70 "
" 8	60 "
" 15	60 "
" 22	60 "
" 29	60 "
Oct. 6	60 "
" 13	80 "
" 20	125 "
" 27	125 "
Nov. 3	100 "
" 10	100 "
" 17	125 "
" 24	150 "
" 30	150 "

The movement of coal Westward by lake, monthly, this year is thus shown:

	Tons.		Tons.
In April	11,405	In Sept	180,641
May	198,976	Oct.	210,856
June	227,231	Nov	148,204
July	113,289		
August	164,836	Total	1,253,538

These figures are from the Custom-House books. The aggregate differs only slightly from the statistics kept by your correspondent.

Notice has been given by the Buffalo, New York & Philadelphia, the Lake Shore, the Nickel Plate, the Grand Trunk, the Michigan Central, and the New York, Lake Erie & Western roads, that hereafter no reduction or concession of any kind in rates or classification will be made from the published West-bound tariff from Buffalo, Black Rock, Suspension Bridge, or Salamanca, N. Y. This notice cancels all special tariffs on cement, iron, plaster, fertilizers, salt, and all other special contracts *except anthracite coal.*

Horsford's Acid Phosphate.

In Impaired Nerve Function.

DR. C. A. FERNALD, Boston, Mass., says: "I have used it in cases of impaired nerve function, with beneficial results, especially in cases where the system is affected by the toxic action of tobacco."

OFFICE OF THE PLYMOUTH CONSOLI DATED GOLD MINING CO.,
23 Nassau St., December 3d 1883

DIVIDEND NO. 7.

The Board of Trustees of this Company have this day declared the regular monthly dividend of one per cent on the capital stock—equal to fifty thousand dollars payable immediately.

W. VAN NORDEN, President.

NOT a day passes but what the announcement comes from several quarters that there has been a temporary suspension at rolling-mills or steel-works. This is followed, generally, within a week or less, by the statement that work has been resumed, after an agreement on the part of the workmen to accept a reduction of wages, ranging generally from 10 to 15 per cent. No one who has during the past year had occasion to buy or sell crude or manufactured iron will be at a loss to understand the reason. The decline in values has been continuous, and in the aggregate large. Manufacturers have seen their margins of profit shrink away, in spite of advantages which close buying of raw materials have given them. They have been forced to go before their workmen with the alternative of asking concurrence in a reduction of wages or of submitting to a closing down of the works. If only from selfish motives, manufacturers are loth to take such a step. It is satisfactory to note that there is not, so far as we know, a single instance or indication of a protracted struggle. The men understand how serious the situation is, and see the necessity of bearing their part of the burden of hard times. On the other hand, this general acceptance of the inevitable, the universal scaling-down of wages, means unfortunately that there is once more room for lower prices for the product of the works. In times of excessive competition like these, a reduction in the cost is a strong temptation to lower offerings. The eagerness to secure orders will too soon induce the producer to sacrifice a part of the ground he has gained by lower wages. Looking the facts squarely in the face, the very circumstance that we hear more of a scaling-down of wages than of shutting-down of works indicates that "bed-rock" has not been reached. When the men begin to feel that they would rather not work at all than work at the wages offered them, and when their employers are indifferent as to their decision, then, in times like these, the reaction is near.

WE are pleased to notice, from a perusal of the Colorado papers, that those who are prominently identified with the great lead interests of that State have taken steps to inquire into the means of seeking relief. A meeting has been held in Denver, at which the following gentlemen were present, so that the gathering was a fairly representative one: W. H. STEVENS, Chairman of the Executive Committee of the Iron Silver Mining Company; JACOB HOUGHTON, Secretary; COLONEL PIERCE, a director; WILLIAM AHRENS, General Manager of the same company; W. L. CHURCH, Manager of the Terrible Mining Company; W. S. WARD, of the Morning and Evening Star mines; TINGLEY S. WOOD, of the Silver Cord; EDWARD EDDY, of the Omaha & Grant Smelting and Refining Company; H. I. HIGGINS, of the American Mining and Smelting Company; HENRY COOM, of the La Plata smelter; CHARLES LIMBERG, of the Arkansas Valley smelter; A. S. HUGHES, of the Denver & Rio Grande Railroad; Mr. KEELER, of the Union Pacific; Mr. CROSBY, of the Burlington & Missouri; and Pool Commissioner DANIELS.

It was decided to form an organization, to be known as the Western Mining and Smelting Association, and a committee, consisting of Messrs. W. S. WARD and CHARLES LIMBERG, was appointed to draw up a constitution and by-laws, to report at a subsequent meeting, while Messrs. T. S. WOOD, JACOB HOUGHTON, EDWARD EDDY, and HENRY COOM were appointed a committee to gather statistics.

This is a movement in the right direction, which we trust will find the general support and co-operation which it deserves. How far it will be able to apply the only remedy which we believe will meet the situation, remains to be seen. There has evidently been some talk of a restriction of production, and it is stated that even now, with the stoppage of the Silver Cord, Henriett, and St. Bernard, with the reduced shipments of the Iron Silver, and the decline in the output from mines in other parts of the State, there has been a decline in the ore production equivalent to the make of 150 tons of bullion a day. We can hardly say, however, how any particular good to the Colorado miners and smelters would result from an agreement to run at half capacity. They will be hardly credited with the generosity of standing in the breach for others, even if more than one half of the producers would agree. It would simply be offering a premium to those who would be unkind enough not to agree with them as to the necessity of the measure. The Missouri, Utah, Nevada, Idaho, and New Mexico producers would give them all the encouragement they wanted, and would go on making and selling lead, the price of which would be maintained by their humane Colorado brethren. As reported, the gentlemen gathered at Denver were unanimous in saying that the last thing they would do would be to cut down the wages of their employés, who are now earning $3 and $4 per day. This sentiment does them credit, but is it business? If they agree upon a policy of restriction, do they put any more money into their workmen's pockets? We believe that their workmen would rather work at a reduction of wages of 30 per cent full-time, than lie idle half the time at present rates. Their argument that every other means of obtaining relief should be exhausted before steps are taken to lower wages is sound. They must, as they are preparing to do, have railroad freights reduced to a reasonable figure, and only those conversant with the facts can tell whether there is much margin or not. It is unjust to assume that the freights from Leadville should be as low proportionately as those from Utah. Shippers from Salt Lake City are said to be enjoying the poor satisfaction of being temporarily able to send base bullion from there to Omaha for $5 per ton, because the Union Pacific and the Denver & Rio Grande roads happen to be on the war-path. This will not last long, and after enough money has been wasted by the railroads, the Utah smelters will be happy in the conviction that they will be made to pay for the piper.

After an adjustment of the freight rates, the Western Miners and Smelters' Association will have to take up the wages question, because we do not believe that a general reduction of the output can or will be agreed upon. There are few mines so situated that, with a plethoric treasury, they can afford to shut down rather than exhaust their resources in putting on the market ore near in value to the present selling price. They are merely taking their chances that they will get something in the future which is now worth little. Their number, though it has been increased recently by an important producer, is limited.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

A Correction.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: The translator of Mr. Cumenge's report on the Rio Tinto, in the JOURNAL for November 24th, quotes Mr. Cumenge's analysis of rich matte produced from rich ores as containing tin, 26·74 per cent. It should be, iron, 26·74 per cent, as may be seen by referring to the original paper, "Pièces annexés," p. xi. Mr. Cumenge's report being in every sense of the word a typical one, he would, no doubt, be pleased to have this error corrected. Truly yours, A. WARTENWEILER.

BUTTE CITY, MONT., Dec. 2.

The Theory of the Action of the Circular Saw in Cutting Cold Iron.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: On several occasions, I have had discussions as to the theory of the action of the circular saw in cutting bar iron (cold), one party maintaining that the saw did not touch the iron; the other, that the iron was cut by the friction of the saw in contact with the iron. Believing that some of your readers will be able to give a decision that will settle the question, will you be kind enough to give this letter a place in your valuable paper? Respectfully, JOHN HENRY HARDEN.

PHŒNIXVILLE, CHESTER COUNTY, PA., Dec. 11.

Sampling Doré Bars.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: It has been asserted, in a letter from London, that if silver bars be sampled from dippings or granulations taken from the black lead crucible while the metal is in a molten condition, true results can never be verified by assays. In consequence, we shall be obliged if you will insert the following three questions in an early issue of your paper, and advise us upon the answers received. Of the three following methods of sampling doré bars of bullion, from which is the most reliable assay to be obtained? 1. By chipping corners of bar? 2. By borings taken from the ends of top and bottom of bar? 3. By dippings or granulations taken from the black lead crucible in which the bar is melted after a thorough stirring, and immediately before pouring the bar?

Yours truly, WILLIAM E. WALL,
Superintendent Alice Gold and Silver Mining Company.

WALKERVILLE, MONTANA, Dec. 7.

The Schwartzkopff Safety Apparatus vs. the Evans Safety-Guard.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Mr. Joseph M. Locke, C.E., M.E., in giving five reasons why the Evans safety-guard, described by him in your issue of December 1st, is superior to the Schwartzkopff safety apparatus, seems to have entirely overlooked that the scales may also be turned the other way. I can give five good reasons why the Evans safety-guard is by far the inferior of the two inventions:

1. Its action depends upon a number of mechanical parts which may get out of order, and are more difficult to examine than the working condition of an electric alarm.

2. The indication of "low water" is very clumsy and not delicate. A considerable portion of the "boiler-tubes" must be exposed before the alloy will liquefy, as, in this case, it is cooled by the surrounding steam, and can only fuse if heated to the temperature corresponding to "undue pressure." Mr. Locke will agree with me that to allow the water in a boiler to sink below the tubes is not good steam-engineering.

3. If the boiler is fired dry, no alarm whatever is given, and should the fireman fail to "see" that the lever of the safety-valve has moved (which may easily occur at night), he will spoil the boiler by continued firing, or have an explosion, in spite of the safety-valve being open, as soon as he pumps water into the red-hot boiler.

4. Without an electric alarm, no notice of the abnormal condition of the boiler is conveyed to the office of the superintendent.

5. The alloy, remaining in contact with another metal—no matter what that metal is—must soon deteriorate, and change its point of fusion, which can not take place in Schwartzkopff's apparatus. This is one of the most serious objections.

No wonder the Evans safety-guard met with "vindictive opposition from large numbers of steamboat engineers." That Schwartzkopff's invention is of greater merit than Mr. Locke is disposed to accord to it, is apparent from its introduction in Europe. To show that some very eminent engineers are using and recommending it, I give the names of a few establishments only which have adopted Mr. Schwartkopff's safety apparatus: The Prussian Artillery-Works, Spandau; Siemens & Halske, Berlin; Siemen Brothers & Co., Limited, London; A. Borsig, Berlin; Bochum Cast-Steel Works, Bochum; Austrian Northwestern Steamship Company, Vienna; the Hamburg Gas-Works, Hamburg; Austrian Alpine Mining Company, Vienna; the Société Industrielle, Warschau.

WASHINGTON, Dec. 13. C. A. STETEFELDT.

The Mine Engineering Profession.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Probably there is no profession, and certainly none of the engineering professions, whose special field of work is so generally poorly defined in the public mind, and so much invaded by men who bear the same relation to the mining engineer that the quacks and the shysters do to the medical and the legal profession. This fact is not as apparent in the East as in the West. Here, we find many surveyors who make a business of surveying mineral claims, and whose education and experience have not extended beyond that class of work, who not only advertise themselves as "civil engineers," but also generally claim the profession of "mining engineers." They are men whose knowledge of mining engineering consists in the ability to distinguish between the different ores common to the immediate district in which they are located, and to map a mine. Any knowledge of geology, assaying, metallurgy, mine timbering, or of any but the simplest problems of underground engineering, is utterly foreign to them. In addition to this class, the mining engineer is obliged to compete with the "practical miner mining engineer," who, while possessing none of the engineering training of the surveyor, and lacking the education necessary to the solution of geological and metallurgical questions, still has the advantage generally of sound common sense and practical experience. He, however, generally fails to take a comprehensive view, owing to his one-sided education and limited acquaintance with different mining sections. In the course of my experience in the Western mining States and territories, I have met many men of both the above types, and believe they number two to every one mining engineer who has earned by education, training, and experience the right to belong to the profession. What has been the result? The public generally accept a man at his own estimate, until they learn to the contrary. Every one calling himself a mining engineer has been employed in some capacity or other, and naturally, in two thirds of the cases, satisfactory work has not been obtained. The public loses confidence, and the profession suffers. As a fact to-day, some Western papers of prominence openly denounce the mining engineer and "expert," whom they regard as one and the same, and warn the investor to steer clear of him. The term "expert" is used most promiscuously, has become of very doubtful and not very reputable significance, and should be abandoned as applied to engineers. While every mining engineer should be an expert in mining matters, very few "experts" are mining engineers.

We have arrived at an era in the mining industry when the services of the legitimate engineer should be in demand. Mining is conducted more nearly on business principles, and is demanding more economical and skillful management than ever before. Investors and owners must see that in mining, as in railroading or manufacturing, success requires the aid of men specially trained for that work, and of practical experience in it, and that the day of the Eastern clerk as mine superintendent, the investor as his own engineer, and of all unqualified engineers has passed. The engineer should receive a reasonable fee for his services, and be consulted not only in cases of the transfer of property, but in all questions of actual mine development, such as the location of shafts and tunnels, the erection of hoisting or milling plants, etc. It is in the wrong solution of such vital questions of daily occurrence that many valuable properties have in the past few years been wrecked or burdened with an expensive system of development.

What, then, are to-day the requirements of a competent mining engineer?

1. A constitution able to stand hard work and privation; good digestion, muscular development, and eye-sight.

2. A scientific training and education, such as is now provided in the mining course in the leading mining schools of this country, namely, the Massachusetts Institute of Technology, and the Columbia College School of Mines.

3. Not less than five years' practical mining experience in the leading mining sections of this country, including work as prospector, common miner, mine foreman or shift-boss, and superintendent. This should include experience in working both bedded and fissure-vein deposits.

4. A character prominent for honesty, self-control, pluck, and perseverance.

The mining engineer who lacks any one of these four requirements is not qualified to practice his profession. I regard the mining engineering profession as becoming more and more distinct from that of metallurgical engineering, and believe they should be separated by our mining schools. Concentration, or the dressing of ores, however, is a branch belonging more particularly to the mining engineer, and a knowledge of that subject, as well as of the principal metallurgical processes, is necessary to him; but his specialty is the mine, not the reduction-works. The metallurgical treatment of mineral products is a distinct industry, and requires special training and experience, differing largely from that of the mining engineer. While the two branches of engineering are closely allied, each is a large field by itself, and either industry will be better served if men are specially trained for its requirements.

DENVER, COLO., Dec. T. E. SCHWARZ, Mining Engineer.

MONUMENT TO THE INVENTOR OF THE HOT BLAST.—A monument in memory of Mr. James Beaumont Neilson, of Queenshill, inventor of the hot blast, has been erected on Barstobrick Hill, Queenshill estate, near Kirkcudbright, by his son, Colonel W. Montgomerie Neilson. The monument is shaped after the pyramid style, and is built of large blocks of whinstone, with granite corners. Occupying a commanding position, it rises to a hight of 55 feet, and at the base is 20 feet square. On the north side is the inscription: "1883. W. M. N. Fecit." On the south side: "Neilson Hot Blast, 1828."

A NEW CARTRIDGE.—Mr. C. W. Curtis, of the firm of Curtis & Harvey, well-known English manufacturers of blasting-powder, is about to bring out a new invention. It consists of an entirely closed cartridge, in which the powder is fired from the outside. This is accomplished by means of a separate "exploder" placed on the top of the charge. This exploder differs from the ordinary fulminate detonator in two important particulars: it is charged with common gunpowder, and it is itself entirely closed. The advantages of a cartridge that has not to be opened to insert a fuse are obvious. The powder can not be brought into direct contact with fire, and none of the grains can be spilled and exposed to sparks and blows, either during transport or while in the hands of the miner. It would seem that this arrangement must give the greatest attainable degree of safety in the use of an explosive. Another advantage of a closed cartridge is, that in wet holes it remains secure against the entrance of water, since nothing is left to the miner's care. The employment of gunpowder in such cartridges in collieries must certainly conduce to the safety of the men.

CARBON DEPOSITS IN INCANDESCENT LAMPS.

In his inaugural address to the Newcastle-on-Tyne section of the Society of Chemical Industry, speaking of Dr. Fleming's experiments with Edison lamps and the copper deposit which takes place in them (*vide* the *Electrician*, vol. xi., p. 65), Mr. Barnard S. Proctor said: "In Swan lamps, the globe contains no material but the carbon filament, platinum wire conductors, and an infinitesimal residuum of air. Dr. Fleming says that when carbon is deposited on the inside of the Edison lamp, it is in a continuous coat, but when copper is so deposited, the molecules appear to be thrown off in straight lines from the point of heated metal, so that a shadow of the carbon filament is thrown upon the opposite side of the globe, the shadow consisting of a line of clear glass upon which no copper has been deposited. In Swan lamps which I have had the opportunity of observing, I have never seen such a shadow in either the carbon or the platinum deposit. My son, Mr. Charles Proctor, who is electrical engineer at the Swan Works at Benwell, informs me that these carbon deposits which occur when a lamp is overheated occur even more in lamps with the highest *vacua* than in those less perfectly exhausted. This would rather discourage the idea of the molecules being carried by currents in the residual air, and as yet we are wanting in evidence of the molecules being thrown off in radiations and equally wanting in any indication of the carbon having been in a truly gaseous condition. As the highest temperature to which the carbon can be raised fails to give any appearance of softening, I think we must give up any idea of the bending noted in 1878 being consequent upon an incipient plasticity; and if the smoky deposit is supposed to be the result of vaporized carbon, we may also suppose that it can not be melted except under the combined action of heat and pressure. Several lamps on the table illustrate the condition of the smoky deposit. There are four in which the deposit has accompanied the formation of an arc and four in which the arc has not been formed or the current has been stopped at the moment of its formation. In none of them can any symptom be observed which would indicate such a radial projection of molecules as to throw a shadow of the filament on the opposite side of the globe. There are also two broken globes, in one of which you may notice a patch of the deposit has been burned off by the heat of a spirit-lamp, showing that the deposit is almost entirely carbon. In the other fragments, the purple-black tint shows that an arc had formed by fracture close to the platinum wire, scattering platinum upon the glass almost free from carbon, as the film is little affected by heat and almost entirely removed by *aqua regia*. These deposits have all been formed intentionally by passing through the lamps stronger currents than they were intended to carry."

THE THEORY OF THE CRUCIBLE STEEL PROCESS.

Professor Ledebur, of the Freiberg School of Mines, is rapidly acquiring a high standing as an authority on matters pertaining particularly to the metallurgy of iron. In a recent issue of *Stahl und Eisen*, he has discussed a subject which will interest American steel-makers. We therefore reproduce a good translation of his paper from *Iron*.

There is not one of the more important metallurgical processes which has been more neglected by investigators than the manufacture of crucible steel. The reasons for the neglect are various. Many manufacturers suppose that the protection afforded by the crucible to the molten metal is sufficient to render any important chemical change impossible. Many smaller works also carry on their operations quite empirically, and do not trouble themselves either about the chemical composition of the charge or that of the finished cast-steel. Large establishments, however, which base their operations upon chemical examination, for reasons unknown to me, prefer to surround their manufacture of crucible steel with a kind of secrecy, even if they open their other departments most obligingly to the inspection of visitors and to scientific investigation. Even the smallest crucible steel-works often believe themselves bound to imitate the example of their larger competitors in this respect.

As is well known, MM. Troost and Hautefeuille have shown that silicon is reduced by carbon from crucibles containing silicic acid, and conveyed to the iron. It may be considered as proved that silicon reduces the property of liquid iron of secreting gases in solidifying, and thus acts beneficially in this respect. The process discovered by MM. Troost and Hautefeuille undoubtedly facilitates the obtaining of close castings in crucible melting; but few reliable data have as yet been published as to how far external conditions—especially the composition of the crucible and the composition of the charge—act upon the reduction of silicon in the crucible. A few experiments of Böker given in Wedding's *Darstellung des schmiedbaren Eisens* have reference only to the carbon contents of steel, and consequently do not permit of reliable conclusions as to the behavior of silicon. Two analyses made in Dr. Percy's laboratory on the influence of an addition of manganese, and which are reported in the above work (page 690), gave results the correctness of which must be strongly doubted (an aluminium contents of 0·12 per cent), and which possess little value because there are no data given of the composition and the quantity of the manganese alloy added.

As the reducing agent for silicon is in any case carbon, it may be assumed at once that this reduction will be greater if crucibles are employed containing large quantities of carbon (plumbago crucibles) than if crucibles are used containing little. The following information supplied by a friend confirms this theory. Equal charges, consisting of 30 per cent of crude steel and 70 per cent of wrought-iron, were melted in three crucibles of different carbon contents. The steel from bauxite crucibles with a carbon contents of 9 per cent contained 0·144 per cent of silicon; from fire-clay crucibles with 28 per cent of carbon, 0·274 per cent of silicon; and from fire-clay crucibles with 39½ per cent of carbon, 0·392 per cent. It is self-evident that the duration of the melting process and the melting temperature must also be of influence upon the reduction of silicon.

As regards the behavior of manganese in crucible melting, it has been proved by various recent examinations of other processes that the presence of manganese in iron may be an effective means of reducing silicon if opportunity is given for the protoxide of manganese formed to become saturated with silicic acid, and there is a high temperature. If spiegeleisen is melted at a high temperature in a cupola, with a lining holding silicic acid, it absorbs silicon, while manganese is eliminated, and may be changed into gray pig-iron. If gray iron containing manganese is melted repeatedly in the cupola, it remains gray all the longer—that is to say, it loses its silicon all the more slowly—the richer it was originally in manganese. It may therefore be assumed that in melting cast-steel in the crucible it would turn out all the richer in silicon the richer the charge was in manganese. In order to practically test this theory, at my request two charges of different percentages of manganese were melted under the same conditions in a large cast-steel manufactory. One charge consisted entirely of hearth steel, containing on analysis 1·29 per cent of carbon, 0·01 per cent of silicon (probably a constituent of the cinder), 0·12 per cent of manganese, and 98·50 per cent of iron. The second charge consisted of similar hearth steel, with the addition of 2 per cent of ferro-manganese, with 4·70 per cent of carbon, 2·07 per cent of silicon, 46·54 per cent of manganese, and 46·48 per cent of iron. Thus the second charge contained altogether 1·34 per cent of carbon, 0·05 per cent of silicon, 1·01 per cent of manganese, and 97·56 per cent of iron. The crucibles used contained in both cases about 39 per cent of carbon. The ingots received and analyzed by me contained:

	C. Per cent.	Si. Per cent.	Mn. Per cent
Without the addition of ferro-manganese	1·24	0·24	0·15
With the addition of ferro-manganese	1·36	0·49	0·75

The considerably larger increase in the percentage of silicon in melting the steel richer in manganese can not be mistaken. It follows, besides, from the analysis that the greater reduction of silicon was not only effected directly by the contents of manganese, but that the close affinity of the manganese remaining in the steel itself promoted the reduction of the silicon through the carbon of the crucible. If manganese serves as a means of reduction, the process taking place is evidently expressed by the formula: $2\,Mn + SiO_2 = MnO + Si$; that is, for 1 part in weight of silicon which is reduced, $\frac{110}{28} = 3{\cdot}93$ parts in weight of manganese must be oxidized. In the case before us, 0·49 — 0·24 = 0·25 per cent of silicon more is reduced in melting manganiferous steel than in melting steel poor in manganese. If this reduction were effected simply by manganese, it would only have required 3·93×0·25 = 0·98 per cent of manganese, which must have been eliminated from the steel, and the manganese contents of the latter could consequently have amounted to only 1·01 — 0·98 = 0·03 per cent, while the percentage was in reality 0·75. It follows from this that only a very small portion of the silicon has been reduced by manganese.

As is well known, a closer affinity exists also between carbon and manganese than between carbon and iron, and the effect of this circumstance may be plainly discerned from the analysis. While in melting steel poor in manganese a slight decrease of carbon is perceptible, manganiferous steel shows a large increase of it, caused by absorption from the crucible containing it.

THE ORIGIN OF GOLD IN CERTAIN VICTORIAN QUARTZ REEFS.

Mr. William Nicholas, geological lecturer at the Melbourne University and at the Sandhurst School of Mines, has read a paper before the Royal Society in Melbourne, entitled the Origin and Growth of Gold and Quartz Reefs or Veins in the Lower Silurian Rocks of Victoria. We quote from it as follows:

"Being deeply impressed with the idea that the 'laminated' quartz reefs are, for the most part, simply transmuted slate-beds, I looked for an explanation of the presence of gold in these reefs. In connection with this subject, I need hardly say that Mr. Newbery's researches, which have been published in your Transactions and the Progress Reports of the Geological Survey of Victoria, have thrown much light, and they may be looked on as standard investigations for reference. He has obtained gold from the incrustations of steam-boilers fed with mine-water, and he said that the late Mr. Daintree found gold in mine-water. It was therefore quite evident that mine-water was also the source of the gold in quartz reefs. Mr. Newbery remarked that organic matter has long been known as an agent for precipitating gold in the metallic state from its solutions, and the conclusion I came to was, that the organic matter in the soft black carbonaceous slate, when this slate was decomposing and changing into quartz, became both the precipitant and nucleus for the extraction of gold from the mineral waters that circulated in the tracks and reefs. I think the black slate, however, contained gold originally apart altogether from the mineral waters; for it is well known that 'casing' slate is frequently very rich in gold, and that too sometimes in very little altered or firm slate rock.

"'Casing' slate is now, as a rule, sent to the batteries to be crushed with the quartz from the reefs. I communicated my ideas on the origin of quartz reefs and gold to Mr. Mica Smith, B.Sc., of Sandhurst, who very kindly offered to make gold solutions for me with which to test the value of my ideas by experiments; and the following are the results of those experiments up to date: No. 1. (Strength of solution, 1½ grains of metallic gold to 1 ounce.) Quantity of solution, 2 ounces of distilled water. In this solution, I placed a cube of galena and some soft black carbonaceous slate which I obtained from the Garibaldi mine, New Chum Reef, Sandhurst. Within twenty-four hours, gold was precipitated on the top edge of the cube of galena, and most plentifully on the black slate, and the next day I observed the whole side of the cube was covered with gold. On the black slate also, gold particles were visible, and just beneath its surface a thin layer of gold had begun to accumulate. I noticed, too, that action had apparently been to a great extent transferred from the galena to the slate. This experiment was begun on May 19th, and I may mention that it was carried out in a glass stoppered bottle from which the stopper had not been removed. Further, so as to assimilate my experiment as closely as possible to nature's conditions, I placed the bottle in the dark. On June 11th, a white spot made its appearance, through its lifting up some of the slate and gold. On the 16th, no change was visible excepting the enlargement of the white substance which swelled upward and spread outward. The body of the mass of slate also appeared to be showing a disposition to become white. This white

Digitized by Google

substance proved to be quartz. A doubt, however, existed whether this quartz was not enveloped in the slate put in the bottle; and must be verified by other experiments before this production of quartz can be announced. No. 2. This solution was identical with that of No. 1, with the exception that I added to it 2 ounces of mine-water, thus reducing its strength by one half. In this solution, I placed two bits of hard black slate taken from the same sample of slate as that used in No. 1. This experiment was begun on May 27th. It was then placed in the dark, and I found on my next looking at it on June 3d that both pieces of slate were covered with a bright gold. On June 10th, this gold coating became of a dull brown color, but bright gold was still visible. On this date, I placed two pieces of hard sandstone in the same solution. On the 24th, the condition of the slate remained unaltered, and the sandstone had deposited on them a few tiny brown spots and what appeared to be pin points of shining gold—doubtful. I also noticed two tiny white spots on one sandstone and one on the other.

"No. 3. Having ½ drachm of the solution of gold left, I placed this quantity in a bottle with two ounces of mine-water on May 27th, and added to it a little fine black slate, I did not observe any change in the experiment until June 24th, four weeks after, when the slate which was lying on one side of the bottle was swelling upward and gold was precipitated on its surface. No. 4 solution same as No. 1, excepting by addition of mine-water. Fine black slate was placed in the bottle sufficient to cover the whole of the bottom to the depth of a quarter of an inch. In a fortnight, a flocculent white substance had formed in the solution and settled around the sides of the bottle in white flakes; the whole of the surface of the slates was covered by a brown deposit in which gold can be seen. It is also visible in the overlying brownish white flaky deposit. In cavities formed by one or two bits of slate resting against the side of the bottle, gold can be seen attached to the black slate. No. 5 solution same as No. 4. In this, I placed sufficient large and small bits of calcite (carbonate of lime) to cover, or nearly so, the bottom of the bottle, which consisted of crystals of calcite got from Victoria Reef, Sandhurst; the mine-water used in Nos. 4 and 5 came from the City of Sandhurst mine, Hustler's Reef, Sandhurst. A disposition in the bits of calcite to turn purple is manifest. The solution still retains its bright yellow color, and a light brown deposit has settled on the calcite.

"No. 6. A cube of galena was placed in this, which has turned to a black-brown color, and to its edges are attached floating dark-brown dendritic forms. Solution, colorless. No. 7. In this, were placed three pieces of arsenical pyrites, got from Hustler's Reef, Sandhurst. Decomposition set in strongly; nearly all the yellow color had left the solution, and brown shadow-like deposits had formed, the specimens were coated with gold, and a few dark dendritic forms floated attached to their angles Gold adhered to the glass near the specimens, and the shadows continued to increase in a ray or star-like form. No. 8. In this was placed finely powdered black slate, carefully examined to prevent any bits of quartz being placed in the bottle. In three days, all the gold was precipitated, and the solution was colorless.

"'However little insight this paper may give as to the origin of laminated or banded lodes in other countries, I trust I have at least produced sufficient facts to warrant me in concluding that Victorian auriferous laminated quartz reefs are simply altered auriferous carbonaceous slates or clayey sandstones, and that through this transformation some of the gold in reefs was obtained by precipitation from the pervading mineral waters. Thus quartz and gold were formed by one operation in nature."

DREDGING AT OAKLAND HARBOR, CALIFORNIA.

At the last meeting of the American Society of Civil Engineers, a paper was read by Mr. L. J. Le Conte, Mem. American Society of Civil Engineers, describing the dredging operations at Oakland Harbor, Cal. The work described was the excavation of a tidal basin, and the deposit of the excavated material on the adjoining salt marshes. The machine used was a pump-dredge with a cutting apparatus consisting of a horizontal wheel with ordinary plows upon its lower face. The rotation of this wheel makes the excavation. Over this cutter and partly surrounding it is a hood, which allows water to enter only from beneath. Over the top of this hood a 20-inch pipe leads up to the large centrifugal pump of six feet in diameter. From this, a line of wrought-iron pipe, supported partly on pontoons and partly on the marsh, extends several hundred feet upon the tract to be reclaimed. The material, after leaving the cutter, is taken up by the water, passes through the pump and through the pipe to its place of deposit, without at any time during the transportation coming to a state of rest. The engines are two 16 by 20-inch engines, used exclusively for driving the centrifugal pump, and two 12 by 12-inch engines for driving the cutting apparatus, swinging the gear, etc. The steam is supplied by two 100 horse-power boilers, generally carrying from 90 to 95 pounds of steam. The amount of material transported with the water runs at times as high as 40 per cent by volume, but experience has shown that, in the material excavated at this point, which is a blue clay mud, it is not advisable to carry more than 15 per cent, particularly in order to secure a uniform distribution at the place of deposit. The total quantity moved by one dredge in eight months was 250,000 cubic yards. The best work in one month was somewhat over 60,000 cubic yards in 230 engine hours; the average distance of transportation being 1100 feet. The greatest distance transported was during October, when 45,000 yards were deposited in 190 engine hours, through from 1600 to 2000 feet of 20-inch pipe. The average daily expense account was stated as approximately $102; but this did not include the cost of the nine or ten men on shore, employed to secure a proper disposition of the material, particularly as the fill approaches completion, nor did it include the cost of retaining-embankments where required. The result of the work was stated to be, with this one pump-dredge, an average of 30,000 cubic yards, measured in the cut at a maximum cost of 10 cents per cubic yard, and in one particular month of 23 days' work, 60,000 cubic yards were deposited on shore at a distance of from 1600 to 2000 feet from the dredge, at a cost of 5 cents per cubic yard. The complete distribution of the material at the place of deposit has been very satisfactory, the result being a cluster of cones whose slopes are very flat—not more than 1½ per cent, and frequently so slight as to appear almost level.

THE LIABILITY OF A BOILER INSPECTION COMPANY.

Before the United States Circuit Court of the Eastern District of Pennsylvania, the case of Bradley and Wife *versus* the Hartford Steam-Boiler Inspection and Insurance Company involved the question of the liability of a boiler insurance company for damages for the loss of life occasioned by the explosion of a boiler inspected by it.

Defendant is a foreign corporation authorized to grant certificates of inspection and insure steam-boilers in the State of Pennsylvania. A certified boiler exploded and killed plaintiffs' child, and they brought suit to recover the value of its life (that is, the value of the child's service to them during his minority had he lived), alleging negligence in the inspection, the certificate granting an extent of pressure the boiler could not safely sustain. Defendant undertook to inspect Gaffney & Nolan's boilers at the corner of Mascher and Collins streets, and in accordance with the city ordinance. The *American Exchange and Review* has abstracted from the charge of Judge Butler to the jury as follows:

1. Did the certificate accord to the boiler a greater capacity of resistance than it would safely bear, thus authorizing its use under a dangerous degree of pressure? And if it did, then

2. Was this the result of negligent inspection?

The burden of proof respecting both questions is on the plaintiffs. You will first inquire whether the plaintiffs have shown that the boiler would *not* safely bear the certified pressure? They called before you several mechanical engineers as experts, some of whom testified, from investigations made after the explosion, that, in their judgment, the boiler-head would not safely sustain the pressure. Some of these witnesses, as the court understood them, did not unite fully in this judgment. This, as you observe, is the opinion simply of skilled and intelligent witnesses, who had no opportunity of examining and testing the head (the only part alleged to be defective) before the explosion. On the other hand, the defendants have called before you the manufacturers of the boiler, who testify, not only that the boiler was constructed of good material, and in the best manner as respects workmanship, but also that they subjected it to the hydrostatic test, and thus actually ascertained that it would safely bear a considerably higher degree of pressure than the certificate subsequently accorded it. The defendants' agents who inspected the boiler and granted the certificate testify that they also subjected it to this test, and ascertained it to be capable of bearing the pressure accorded with safety. The engineer who was first placed in charge testifies that, for the several weeks he ran the engine, the boiler sustained this pressure with safety. Several witnesses have testified that, with a view to ascertaining what pressure such a head would bear, a short boiler, with a head precisely like this, was manufactured after the accident, and subjected to the hydrostatic test, under the supervision of the city inspector; and that it actually bore between four and five hundred pounds to the square inch. The defendants also called experts, who, from the appearance of the boiler, expressed the judgment that it would safely bear the pressure certified.

The defendants were not insurers, as respects the plaintiffs. It was their duty to inspect and test the boiler, as has been explained to you. If the want or insufficiency of resisting capacity could be discovered by such inspection, they should have discovered it, and a failure to do so, under such circumstances, would be negligence. They were not required or authorized, however, to cut or chip the iron, and thus ascertain its quality, but to examine the boiler and its workmanship carefully and intelligently, and see whatever could thus be seen, and to subject it to the prescribed hydrostatic test. If they did this, and certified according to their best judgment thus formed, they are not responsible, no matter what latent defects may have existed.

Can you say that the boiler was subject to any defect discoverable by such an inspection? The head was of cast-iron, flat, with the flange turned inward. If such heads as you find this to have been were in common use, and thus approved by manufacturers and the trade, the defendants can not be held guilty of negligence in failing to condemn it, on this account. That such heads were in common use at the time, the testimony on both sides would seem to put beyond doubt. That other heads, of a different type, might be safer, or that experts differ in judgment on this subject, is unimportant. The defendants can not be found guilty of negligence in failing to condemn a head such as was in general use, and thus proved to be reasonably safe, or at least shown to be so esteemed.

The plaintiffs, however, contend, and have endeavored to prove, that this head, aside from its kind and material, was defective in manufacture—in that the man-hole plate, as they assert, was irregular, or uneven, on its surface, so that when bolted down upon the head, to make a close joint, it would strain the metal of the head; and in some other minor respects. While two, and possibly more, of the plaintiffs' experts testify to such defects of construction, others, and probably a larger number, of the plaintiffs' witnesses, who had an equal opportunity of examining the head, testify, either that they did not find these defects, or that they attached no importance to them. On the other hand, the defendants have exhibited the man-hole plate to you, and called witnesses, who, examining it in your presence, say it does not exhibit such uneven surface, and that it can not have been altered in this respect since the accident.

To the court, the exhibition of the plate, with this testimony, seems to be a complete and conclusive answer to the plaintiffs' allegation in this regard. You will say, however, whether it is so or not. Other experts called by the defendants tell you that there were no defects in the boiler-head, such as the plaintiffs ascribe to it, nor any other that a careful and competent inspector could have discovered. The City Inspector, Mr. Overn, called by the plaintiffs as well as the defendants, tells you distinctly and emphatically that no imperfection of any description could have been discovered in it before the explosion. He further tells you that he, as inspector, would certainly have passed it, and accorded the pressure certified; that the broken parts, examined by him after the accident, showed plainly that the explosion resulted from faultiness of the iron alone, which faultiness no previous inspection could have revealed. The defendants' agents, who inspected and tested the boiler, described to you how they did it; testify that they were careful in all respects; that they could discover no defect, and that it safely bore the prescribed test. The court sees nothing to justify the suggestion that these inspectors were wanting either in experience or intelligence.

Counsel for plaintiffs presented three specific exceptions to the charge of the court. Verdict for defendant.

A SUGGESTED CURE FOR BLAST-FURNACE CHILLS.*

By Henry M. Howe, A.M., M.E., Boston, Mass.

The object of the present paper is to suggest injecting into the hearths of iron blast-furnaces, whose temperature has become unduly lowered, some form of fuel whose calorific intensity under the peculiar conditions existing there is considerably higher than that of liquid petroleum, the use of this substance for melting out chills having grievously disappointed the high hopes which were at first entertained of it.

A chill being a fall of the temperature below that needed for the complete liquefaction of the slag, which requires, according to Plattner, about 1800 degrees C., one would suppose that the chief thing to be accomplished in curing it would be to raise the temperature in the crucible of the furnace. The most obvious ways of doing this seem to be to raise the temperature of the blast, and to increase the amount of fuel in the crucible itself. Simply increasing the rate at which the blast enters the furnace, if carried beyond a certain point, should lower the temperature in the crucible. The existence of a chill shows that the fuel is arriving too slowly at the tuyeres. If air be introduced so rapidly as to be in excess of that required for the combustion of the fuel, all that excess will simply lower the temperature around the tuyeres, carrying the region of intense heat upward, and weakening its intensity by increasing its size. Up to a certain point, increasing the rate of introducing the blast will increase practically *pari passu* the rate at which the fuel reaches the tuyeres. But when mechanical obstructions, which so often accompany chills, retard the descent of the fuel, there must be a point beyond which this does not hold good, and beyond which further increments in the rate of introducing the blast will not correspondingly increase the rate of descent of the fuel.

Up to a certain point, blowing on a match, a candle, or a fire will cause it to burn more intensely; beyond that point, the more you blow, the lower will be your temperature, till finally your fire, your candle, or your match is blown out.

Apparently somewhat the same thing is liable to take place in the crucible of a chilling blast-furnace. But one would expect that any chill could be melted out if you could considerably increase the rate at which both the fuel and the blast reach the tuyeres, provided that their combustion yields heat enough to raise its own products to a temperature well above the slag melting-point. This should be the more readily effected if the rate of arrival of the blast and fuel be increased in a higher ratio than the rate of arrival of the ore and flux.

FUEL AND CONDITIONS.	TEMPERATURE REACHED BY PRODUCTS OF COMBUSTION.	
	On complete combustion to CO_2 and H_2O.	On subsequent reduction to CO and H.
Pre-heated petroleum vapor, after Dulong's law, taking calorific power of C. at 11,214.....	3,950° C.	2,511° C.
Cold liquid petroleum.....	2,845	1,561
Pre-heated petroleum vapor, assuming its calorific power to exceed that of cold petroleum by its sensible heat above 100 degrees C., plus total heat of evaporation at 100 degrees C.....	3,050	1,737
Acetylene.....	3,840	2,474
Fine anthracite blown through tuyeres.....	3,389	2,114
Incandescent anthracite reaching the tuyeres in the normal way....	3,404	2,182
Ordinary producer-gas.....	2,379	1,265

Apparently the liquid petroleum has not in general yielded a temperature far enough above the slag melting-point to produce the desired effect, and I think that a little reflection explains clearly why it has not, and suggests the use of some other forms of fuel. I believe that much at least of the disappointment has been due to the kind of fuel injected, to its high percentage of hydrogen and low calorific intensity; and that a fuel of higher calorific intensity would in many cases have accomplished what the petroleum failed to effect.

In the first place, as the petroleum is injected cold and liquid, a great amount of heat is at once consumed in heating and subsequently in gasifying it. The amount of heat thus consumed is so great that the remainder of the heat generated by the combustion of the petroleum is not sufficient to raise the products of that combustion to the slag melting-point, except in the very small region where they remain unreduced from CO_2 and H_2O to CO and H.

Just how great the total heat of evaporation of ordinary petroleum is, I can not say, but there can be no doubt that it is very considerable. Mr. Joshua Merril, an authority in such matters, informs me that, from his prolonged experience, he considers it at least as great as the total heat of evaporation of water at 100 degrees C. Assuming it at this figure, pre-heated vapor of petroleum should raise the products of its own combustion in the blast-furnace to a temperature some 176 degrees C. (307 degrees F.) higher than cold liquid petroleum would.†

This seems to be about the lowest value we can assign to the difference between the temperature produced by the combustiou of cold liquid petroleum and that produced by pre-heated petroleum vapor.

Now, although the bituminous coals have calorific powers considerably in excess of those which Dulong's law‡ would assign them, that of petroleum is much lower than this law would imply.

This may be explained as follows: Dulong's law employs the calorific power of *solid* carbon, but of *gaseous* hydrogen. Now, if we regard the bituminous coals not as strictly solids, but as merely extremely viscid liquids, like the bitumens into which they shade, the calorific power of their carbon should be greater than that of solid carbon, while that of their hydrogen should be less than that of gaseous hydrogen, the differences corresponding roughly in the first case to the latent heat of liquefaction of solid carbon, and in the second to the latent heat of gasification of liquid hydrogen. On this view, the ratio of the actual to the theoretical calorific power should increase in the case of liquid and subliquid hydrocarbonaceous fuels with the percentage of carbon they contain; and this is the case, roughly speaking, the actual caloric power being much greater than that calculated in the case of the coals, and much less in that of the petroleums.

If, as I believe, this is the true explanation of the low actual calorific power of liquid petroleum, we may conceive that gasified petroleum might have a calorific power approximating that which Dulong's law would give it, using in that law the calorific power of gaseous carbon, 11,214, instead of 8080, that of solid carbon to which this law was intended to apply. On these suppositions, the vaporized petroleum should yield in the blast-furnace a temperature nearly 100 degrees C. (1800 degrees F.) higher than cold liquid petroleum would.

This supposition is undoubtedly extreme, and it seems probable that the temperature attained with our pre-heated petroleum vapor will be somewhere between that just given and that previously assigned it, on the supposition that the total heat of evaporation of petroleum equals that of water. The temperatures corresponding with these two sets of suppositions are given in lines 1 and 3 in the accompanying table.

The preceding statements suppose that the CO_2 and H_2O produced by the combustion of the petroleum are completely reduced to H and CO within a short distance of the tuyeres. The researches of Ebelman show that this reduction took place within 17 inches of the tuyeres in a furnace in normal working. But, as in our case, the chemical composition of the two fuels (and hence of their products of combustion) is identical, the less complete is this reduction, and the more CO_2 and H_2O remain unreduced, the more will the temperature produced by pre-heated petroleum vapor exceed that produced by cold liquid petroleum.

Thus, to repeat, if the products of combustion be completely reduced to CO and H, cold liquid petroleum can not of itself produce a temperature as high as the slag melting-point, even if no heat be lost by radiation and conduction; but pre-heated gaseous petroleum can raise the products of its partial combustion higher, perhaps only to the slag melting-point, but perhaps much beyond it, according to the calorific power which we assign to it.

Now this difference between the temperatures attainable with liquid and vaporized petroleum may well enable the latter to succeed where the former fails.

It may be objected that in distilling the petroleum we may materially lower the proportion of C to H which enters the furnace, since many of the hydrocarbons which arise from its distillation are split up by heat, yielding portions of solid C, which may remain in the retort. To minimize this separation of C, the petroleum should be very rapidly distilled, and as rapidly withdrawn from the retort. To understand this objection, it must be remembered that in burning the petroleum it is only the combustion of its C to CO that creates a net gain of heat in the crucible of the furnace. The H, though burned at the tuyeres to H_2O, is immediately reduced to H by the surrounding fuel, its reduction abstracting as much heat as was produced by its combustion, so that it really adds no more heat directly to the crucible taken as a whole than so much N would.* Furthermore, by its great specific heat, more than ten times greater than that of any of the other substances in the furnace, it has a powerful effect in dragging down the temperature. It seems clear, therefore, that, for the purpose we are considering, H is a far less desirable element than C, and that *cæteris paribus*, the smaller the proportion of H to C in the fuel, the better.

But the proportion of H to C in the vapor differs greatly during different stages of the distillation, and, by diverting the vapors which pass over during the early stages when they are richest in H, and blowing into the furnace only those richest in C, we may hope to bring the average proportion of H to C in our petroleum vapor considerably below that which exists in the original petroleum. This would produce a temperature still further in excess of that attainable with cold liquid petroleum than has been already indicated, and perhaps even approximating the excessively high point reached by the products of combustion of acetylene, given in the fourth line of our table.

The same thing would be accomplished by gasifying and injecting the heavy crude oils produced in refining petroleum, which are much richer in carbon than the original petroleum is. Indeed, even if these oils were introduced cold and liquid, they would produce higher temperatures than liquid petroleum would.

The calorific powers of three of the gaseous hydrocarbons, marsh-gas, olefiant gas, and acetylene, have been actually determined. The proportion of the actual to the theoretical calorific power, calculated by Dulong's law, is by far the greatest in acetylene (the richest in carbon), and much the lowest in marsh-gas (the richest in hydrogen). Analogy would lead us to expect correspondingly high actual calorific powers in the other hydrocarbons which are rich in C.

Another consideration points in the same direction. In addition to their needing higher temperatures, it is highly probable that these hydrocarbons, rich in C, require a greater amount of heat for their distillation than those rich in H. This means that their latent heat of gasification is greater, and hence that the excess of their calorific power in the gaseous state over that in the liquid state is also greater than in the more easily volatilized compounds rich in H.

The fact that the proportion of the real to the theoretical calorific power is greater in the hydrocarbons rich in C than in those rich in H would further reinforce the already very strong probability that, with the former class of fuels, a much higher temperature will be reached than with the latter, by the products both of complete combustion to CO_2 and H_2O, and of the subsequent reduction to CO and H; and it increases the difference we may expect to find between the temperatures attainable with these two classes of hydrocarbons.

* Read at the Boston Meeting of the American Institute of Mining Engineers, February, 1883.

† The assumptions on which this and the subsequent statements concerning the temperature produced by combustion are based are given in full in an appendix. The details of the calculations are given in a second appendix.

‡ Calorific power = $8080\ C + 34{,}462\ (H - \frac{O}{8})$.

* It, however, indirectly contributes to the heat in the crucible. For every portion of H, as well as of C, thus introduced, we have a corresponding portion of combustible gas added to the gases issuing from the throat, which, by its combustion in the hot-blast stoves, adds to the heat of the blast.

Digitized by Google

Let us take the case of acetylene, whose behavior analogy leads us to expect that that of the hydrocarbons of similar composition would resemble. Not only is it very lean in H, having only 7·69 per cent, while crude petroleum has about 15 per cent, olefiant gas 14·3 per cent, and marsh-gas 25 per cent, but it is exceedingly stable, parting with its carbon slowly and only at a high heat. Moreover, it has an exceedingly high calorific power. While crude petroleum has actually 85 per cent of the calorific power which Dulong's law would assign to it, olefiant gas 81·8 per cent, and marsh-gas 76·8 per cent (for the latter two compounds substituting the calorific power of gaseous carbon 11,214 in place of that of solid carbon 8080), acetylene has 92 per cent and 118 per cent respectively, as we assign to the calorific power of C in Dulong's law 11,214 or 8080 units.*

So great is the calorific power of this gas that it would be capable of raising the products of its complete combustion by air to 3840 degrees C.; and even after being reduced to CO and H by the incandescent fuel in the blast-furnace, they should reach a temperature of 2474 degrees C., nearly 700 degrees above the slag melting-point, and nearly 900 degrees C. (1620° F.) above that attainable with cold liquid petroleum. Acetylene is readily produced from petroleum, which, indeed, seems to be its most economical source.

But we may obtain a still lower ratio of H to C by employing another class of fuel. If finely powdered anthracite, coke, or charcoal could be introduced into the crucible in large quantities, it would raise the products of its combustion to a temperature far above that attainable with pre-heated petroleum vapor of the composition of crude petroleum, and very nearly as high as that which is developed by the combustion of the incandescent fuel which is charged at the tunnel-head and reaches the tuyeres in the normal way. What this latter temperature actually is, we do not know. If all the heat were utilized in heating the products of combustion, and if the specific heats of the substance concerned were the same as at ordinary temperature, we should look for a temperature of about 3404 degrees C. on complete combustion to CO_2, and of 2182 degrees C. on the subsequent reduction to CO, were it not for dissociation.

The experiments of Bell show that the temperature of the slag, which roughly represents the average temperature of the crucible, is far above the melting-point of wrought-iron (say 1600 degrees C.), as a bar of that metal inserted in a slag as it ran from the furnace was rapidly melted, collecting in a basin farther on.†

Cailletet found that platinum, whose melting-point is estimated at about 2600 degrees C., melted rapidly at a point about seven inches in front of the tuyeres.‡

Of the three, anthracite, charcoal, and coke, the former should yield the highest temperature on account of its high calorific power, which is probably considerably above that which Dulong's law would assign it.

One can hardly believe that the mechanical difficulties in the way of introducing large quantities of finely-divided fuel are really insuperable. If they can be overcome, I can see no reason why this expedient should not enable the iron smelter to obtain a temperature in his crucible sufficient to melt out any chill or overhanging scaffold. One consideration inclines me to believe that such an introduction of extraneous fuel should be even more efficient in melting out chills and scaffolds than a partial breaking of a scaffold itself would be. If a scaffold is partially broken away, allowing the fuel, ore, and flux to fall into the crucible, as they were presumably charged several days before, and, indeed, before the chill occurred, they will simply arrive in the proportion needed for the regular working of the furnace. (Indeed, the very fact of chilling indicates that the fuel may not have been even in sufficiently large proportions for regular working.) That is, the fuel which is precipitated into the hearth will only be in sufficient proportion to heat and melt the ore which enters the hearth with it, and, by making up for the losses by radiation, conduction, and convection, to prevent the temperature from falling. But there will be no excess of fuel to perform the extraordinary work of raising the already lowered temperature, and of heating and melting large masses of chilled and solidified matter. Our extraneous fuel, however, injected directly into the crucible, not being accompanied by any other matter which absorbs heat in being heated and melted except the blast, generates an abundance of heat which is at liberty to raise the lowered temperature around it, and to heat and melt obstructions. All the heat it generates over and above that needed for raising the products of its own combustion above the slag melting-point is directly available for overcoming the chilled condition of the furnace.

Ordinary producer-gas, if made from anthracite, coke, or charcoal, consists almost wholly of N and CO, with a small amount of CO_2. This gas, introduced into the blast-furnace, could yield no net gain of heat from chemical action: although its CO would be oxidized to CO_2, it would be immediately reduced to CO again. Hence it is not suitable for introducing into our crucible. If the gas were made from bituminous coal, it would be but little better; it would then, indeed, contain a small amount of unoxidized C combined with H, whose combustion to CO would yield some heat, but far from enough to raise to the slag melting-point the immense quantities of inert CO,H and N accompanying it.

The most beautiful way of suddenly raising the temperature of the crucible would be to increase the proportion of O in the blast. The great amount of N in the blast has a most powerful effect in dragging down the temperature, forming, as it does, the great bulk of the products of combustion. Here, as in so many other operations of metallurgy and industrial chemistry, the discovery of an economical means of producing oxygen, or of even slightly increasing the proportion of oxygen in the air, will be an incalculable boon.

To sum up: cold liquid petroleum and ordinary producer-gas, far from having heat to spare, do not generate enough heat to raise the products of their combustion and subsequent reduction to CO and H even as high as the slag melting-point. A somewhat higher temperature should be reached by injecting the crude heavy oils produced at the refineries. Pre-heated petroleum vapor, on the other hand, especially if the proportion of H it contains be materially diminished in either of the ways indicated, is not open to this objection; and finely-divided anthracite, coke, and charcoal would yield a very great excess of heat over and above this requirement.

DISCUSSION.

Mr. W. F. Mattes, Scranton, Pennsylvania: There is one point that I would like to call attention to: chills of this character are usually caused by scaffolding. The scaffold prevents a regular descent of fuel to the place in the crucible where it should do its work, and during the prevalence of the scaffold the supply of carbon in the hearth is much diminished, with the result that the proper reducing atmosphere is not maintained. Now it seems to me that the injection of vapor of petroleum into the hearth, in the manner proposed, will fail to supply the one condition that is absolutely essential, namely, an active reducing atmosphere at that point. It might answer to call upon the fuel to carburize the products of the vapor combustion, provided there is sufficient carbon before the tuyeres. But usually that carbon is lacking, and then the carburization will probably occur higher in the furnace, perhaps at the expense of the fuel at the critical point whence the mischief originated, and any good effects are likely to be merely local and not at the right place. If the obstructions at the boshes can be broken, chills in the hearth will rapidly melt away.

Mr. Howe: The notion that the introduction of carbon and hydrogen—be they gaseous, liquid, or solid—into the crucible will weaken the reducing action there, and so increase the tendency to rob the parts above of their carbon, is utterly untenable. It is an increase in the proportion of oxygen introduced, not of such powerful reducing agents as carbon and hydrogen that would weaken the reducing conditions.

Doubtless you should have a reducing atmosphere with your high temperature, but a little reflection shows that we may hope for both. As the gentleman says, if you keep your petroleum as petroleum, you get no heat from it; if you oxidize it to CO_2 and H_2O, it will not help your reducing conditions; but if you oxidize it to CO, you will increase both your heat and the strength of your reducing conditions. You will not increase the proportion of CO_2 in the crucible unless you increase your blast by an amount which is more than the equivalent of the petroleum injected.

The gentleman seems to agree with me that chill is due to the lack of fuel at the tuyeres, and he rightly says that, if the obstructions at the boshes can be broken, chills in the hearth will rapidly melt away. This is because fresh fuel will arrive there. Now I simply propose that, when you can not get fuel from above, you should force it in from below, and that you should use a fuel of high calorific intensity.

Perhaps he is confused by the idea that it is necessary to have solid carbon at the tuyeres in order to obtain an atmosphere of CO. The gaseous C and H of the petroleum also reduce CO_2 to CO. It is not necessary, as he fears, to call on the solid fuel to perform this reduction. If there should not be enough solid fuel in the hearth to accomplish this, which I consider most unlikely, then the unoxidized portions of the petroleum will reduce the CO_2 and H_2O produced by the complete combustion of the remainder. H and CO_2 can not coexist at these temperatures.

The obscurity and confusion disappear if we remember that the calorific effect and the effect on the chemical compositions of the atmosphere of the furnace caused by introducing petroleum vapor should be parallel with that of introducing incandescent fuel. Indeed, we may here regard petroleum vapor simply as a manageable form of carbon, diluted indeed with a little H, whose presence yields no net gain of heat, but serves to intensify the reducing conditions.

Mr. Mattes: With reference to reducing the products of combustion by unconsumed vapor, it may be noted, first, that as the oxygen supply is continuous with that of the petrolum gas when the latter is in excess, its combustion will yield carbonic oxide and probably steam, but not carbonic acid; and secondly, that the decomposition of the steam by unconsumed petroleum gas does not produce the same effect as if accomplished by incandescent fuel, because the gas does not carry the surplus temperature of the latter. After the reduction of the steam, we shall have a mixture of nitrogen, carbonic oxide, and free hydrogen, which is certainly a very desirable atmosphere if obtained in connection with high temperature.

When, as sometimes happens, a scaffold or a fragment slips into the hearth with plugging effect, the obstruction must be directly attacked by the most available means. Under such conditions, a powerful blow-pipe jet will be a valuable agent, regardless of the composition of the products of combustion. But this treatment should cease when the immediate object is attained; otherwise, the trouble at the boshes may be aggravated and the second stage be worse than the first. When once the obstructions are sufficiently broken to bring within reach a body of incandescent fuel, no reagent is so safe and effective as the heated blast.

I had understood Mr. Howe's proposition to be the introduction of a mere jet of petroleum vapor to be oxidized by the blast of the tuyeres. Its introduction in excess is a different matter, and, if the heat calculations are correct, removes the chemical objection, while increasing the practical difficulties of its application. One of these difficulties is, to gauge correctly the relative percentages of gas and blast; and this will not be met by rapid analyses at the top, because they can not locate the reactions.

It may be interesting to note in this connection the frequent success that has attended an introduction of steam into the hearth for the purpose of breaking a scaffold. The usual method has been to introduce the steam into the blast-pipe before entering the ovens; but in a recent and very successful case, the steam-pipe (1 inch diameter, with ¾-inch nozzle) was carried to the nose of a tuyere and opened full to a boiler close at hand, with 115 pounds pressure, for two or three hours at a time. There is reason, however, to believe that, in every case where steam has proved efficacious, the scaffold-ring had closed rapidly, imprisoning a body of incandescent fuel below sufficient to decompose the steam without undue cooling; thus yielding, still at high temperature, a mixture strongly reducing and very penetrating.

Mr. Howe: I do not know on what ground the gentleman says that petroleum vapor in excess will not produce CO_2 to be immediately reduced to CO: we know that solid fuel, no matter in how great excess, does yield CO_2, which is reduced by that excess.

The difference between the effect of the decomposition of steam by

incandescent fuel and by red-hot petroleum vapor is much less than might be supposed. If we admit a difference of 500 degrees C. in the temperature of the solid and the gaseous reducing-carbon, that 500 degrees would produce only a difference of some 40 degrees C. in the temperature of the resulting products of combustion, so small a proportion does the weight of the reducing C bear to that of the whole of the products of combustion.

While I do not pretend to say that plenty of practical difficulties would not arise on attempting to carry out such a scheme as I suggest, yet I do not think that one of them will be that which Mr. Mattes has specified—gauging correctly the proportions of gas and blast. While, as I have said, you can have an excess of blast, you can not have, in the ordinary working of a furnace, an excess of fuel, because the fuel will only descend to the tuyeres as fast as it is burnt there; you can not make it descend faster. So injecting our petroleum will retard the descent of the solid fuel by consuming a portion of the blast and leaving so much less for the solid fuel. But you can not get an excess of petroleum over blast into your crucible until the petroleum is in such enormous quantity that it consumes all the blast that enters, leaving none whatever for the solid fuel. To do this would require an amount of petroleum which no one in his senses would dream of injecting.

I can see no difficulty in the way of controlling operations by means of rapid analyses of the atmosphere in the crucible, drawing off samples through holes pierced in its sides.

Mr. R. P. Rothwell, New York: I would ask whether Mr. Howe has considered the use of the mixture of carbonic oxide, known as water-gas, for this purpose. The temperature of combustion is higher, if I remember the figures, than the temperature of combustion of vapor of petroleum, and it may be available here. We find it in similar uses in some other processes requiring high temperature. It is a cheap, economical fuel to procure or manufacture. I have nothing more definite than this mere suggestion to make, as I have not the figures at my command, but I believe its temperature of combustion is very considerably higher than that of petroleum or coal-gas.

In some recent experiments that have been made in Germany with this water-gas, they have injected the gas along with the air mixture, either combining it before injection or while it is being injected, and in that way they obtain an extremely high temperature. Whether it would be applicable to the case under consideration I can not say positively.

Mr. Howe: Water-gas consists mainly of CO and H, with small portions of N and CO_2. On account of its freedom from N, its complete combustion of air causes a higher temperature than either C or H. But its introduction into the blast-furnace can cause no net gain of heat there, since, though burnt at the tuyeres, it will be again resolved into its original condition by the solid fuel surrounding it, and the decomposition of the products of its combustion will consume exactly as much heat as was given out on its combustion. The oxidation and subsequent reduction, the generation and absorption of heat, would take place within such a short distance of the tuyeres that probably no useful effect is to be expected from its use. Indeed, as its initial temperature would be lower than that of the crucible itself, it would, in being raised to that temperature, absorb a certain amount of heat, and thereby lower the temperature of the crucible taken as a whole.

Mr. C. Constable, New York: I would suggest that when we speak of a furnace chilling we give the impression that the furnace is likely to go out. It seems to me that "chilling" is commonly, at the outset, the result of driving the point of combustion up into the furnace, and the word is perhaps a misnomer, since the combustion is still going on. Furnaces have been, of course, banked up for six months at a time, and have started off well again, making foundry iron. So that it is not very easy to put out a furnace, to chill it, provided air is excluded. The chilling is rather the apparent cooling of the hearth only, and because the burning-point has been merely driven higher up by an excess of air, as I believe. The hearth, like that of any furnace, is only capable of burning so much fuel per hour; and if an excess of air is blown in, it will burn the fuel that is higher up in the furnace, raising the heat on the boshes and rendering the stock sticky. The danger, then, is, that the stock may scaffold. If the original causes are not removed, the tendency at first to "hang" and "slip" becomes aggravated, and a permanent scaffold is formed, which, if bad enough, may put the furnace out, it is true. At this stage, Mr. Howe's plan may come in play. But when the first indications of the chilling of the hearth are met by a reduction of the revolutions of the engine (to suit the condition that less fuel is reaching it), and, where possible, by an increase in the heat of the blast, I think many of us have not only found relief, but have reduced the tendency to scaffold and chill. What I would call attention to is that, if taken in the first stages, as suggested, serious scaffolds, such as Mr. Howe is treating of, would seldom occur.

Mr. Howe: Doubtless some scaffolds and chills can be remedied in the way the gentleman advises, but many others can not. If you are scaffolded so that coal can not fall to the tuyeres, merely slacking your blast will not bring your coal down to the tuyeres, nor will it raise the local temperature.

If the amount of fuel arriving at the tuyeres in the unit of time is so small that its combustion (even when no excess of air is injected) does not generate enough heat to raise to the slag melting-point the amount of burden which arrives at the tuyeres in the same unit of time and to restore the heat lost by radiation, conduction, and convection during that time, then your furnace must chill and eventually go out unless you increase the rate at which the fuel arrives at the tuyeres, or raise the temperature of the blast, or otherwise increase the amount of heat in the crucible. If you can not bring more fuel in from above, bring it in from below, but gasify it outside your furnace, and do not lower the temperature of your furnace by gasifying your fuel inside it.

WITH the growth of the Western anthracite business, a matter is assuming greater importance to which some of our ingenious inventors should direct their attention. What is wanted is some machinery that will automatically load any kind of a railroad car that may come to the breakers, so that there will be no trouble in loading with hard coal grain cars returning Westward. There is a rich harvest in store for those who succeed in devising a really meritorious machine.

THE HOISTING-ENGINE OF THE BINDWEIDE MINE, GERMANY.

(WITH SUPPLEMENT.)

The engine of the Bindweide mine was designed to afford the means of hoisting the ore for an estimated period of working of twenty years from a maximum total depth of 286 meters, or 200 meters below the tunnel level, the capacity being 40 cars holding 13 tons of iron ore each, per hour. The work of the engine was to include also the hoisting of the coal for the boilers from the tunnel level to surface, and hoisting rock to surface to be delivered to the dump. The specifications called for direct-acting engine, with valve-gear. Cylindrical drums, 3·4 meters in diameter, were chosen. The steam pressure available was from 6 to 7 atmospheres. Taking the weight of the empty cars at 300 kilograms, the maximum load of ore or rock at 1300 kilograms, and the weight of the cage at 500 kilograms, then the maximum load on the wire rope at a point immediately above the cage would be 2·1 tons. In order to have a factor of safety of 10, a 25-millimeter round crucible-steel wire rope was chosen, the manufacturers claiming for it a tensile strength of 27,000 kilograms. Its weight was 1·8 kilograms per running meter, so that, at a maximum depth of 286 meters, the greatest load on the rope, including its own weight, will be 2·615 metric tons. The width of the drums was made 0·8 meter, and the dimensions of the steam-cylinders were made 0·5 meter diameter and one meter stroke. Assuming the useful effect of the engine to be 60 per cent when starting with only one cylinder at work, the other being on its dead-center, and taking the useful effect to be 75 per cent while hoisting, both cylinders doing their work, then the engine will be found powerful enough to start the work with one cylinder, and to hoist it with both cylinders, cutting off the steam at one quarter of the stroke. This is irrespective of any effort to counterbalance the weight of the rope. With a back rope, a pressure of five atmospheres would suffice to do the work. The Gooch valve-gear was adopted, and permits of cutting off at a range between 0 and 85 per cent of the stroke. The cut-off gear is not automatic, the engineer gradually varying it by means of a lever during the stroke. Indicator diagrams taken show that the engine is well designed. There is a slight defect in the admission of the steam, when the cut-off takes place at an earlier part of the stroke, which is due to the use of the Gooch gear.

THE TRANSMISSION OF ENERGY.—It is well known that the town of Geneva is about to erect large works on the banks of the Rhone, the waters of which they intend to utilize for distributing and supplying motive-power throughout the town. Before finally settling the method of utilizing the water-power, they appointed a committee to consider the matter. This committee was composed of MM. Legler, Achard, Pictet, and Turrettini. These gentlemen drew up a report in which they considered the various methods that might be adopted, and, among others, that based on the generation and distribution of electrical energy. One great obstacle to this method was, however, in their opinion, the loss that occurs in the distribution of electricity. "This loss," the report says, "is due to three prime causes: the heating produced by the resistance of the generator, the heating produced by the resistance of the cable, and the heating produced by the resistance of the receiver. These three factors, to which must be added the relatively small amount of friction in the two machines, are the principal cause of the loss of power, which must not be overlooked; for in the celebrated experiments of M. Marcel Deprez at Munich, and at the Gare du Nord, at Paris, they amounted together to about 70 per cent, thus leaving a useful return of 30 per cent only. It is but just to mention that M. Deprez had been pleased to exaggerate the difficulties in his experiments by employing iron cables and by trying to generate a difference of potential of several thousand volts in one machine alone, which rendered it very delicate, and reduced to a great extent the power obtained, owing to the insufficiency of the insulation of the wires of his machine in the presence of such colossal differences of potential. The distance to which M. Deprez transmitted energy was 8·5 kilometers. It is unlikely that in Geneva we should have to transmit so far from the generating station; therefore the problem is to a certain extent simplified." The report further considers that it would not be good to have a higher electro-motive force than 500 volts, in view of possible accidents to persons. For the present, therefore, there does not appear to be any chance of Geneva utilizing its water-power to generate electricity and distributing the latter. The report is in favor of the adoption of a system of transmitting water under pressure, to be utilized as required.

FURNACE, MILL, AND FACTORY.

The Colliau Furnace Company, of Detroit, Mich., has now in course of construction two of its largest size cupolas for the Frankfort shops of the New York, West Shore & Buffalo Railroad.

The converting works of the Scranton Steel Company averaged fifty-two heats per turn last week, a record which, so far as known, has not yet been beaten except by themselves.

The Norway Iron-Works, South Boston, will close its operations under the name of Naylor & Co. the 1st of January. The works were built in 1854 and completed in 1855 by Henry S. Washburn & Co., and shortly after passed into the hands of Naylor & Co., an English firm with agencies in several cities besides Boston. The place was built under the supervision of Hon. Thomas Gogin, and the extensive improvements carried on since that period have still been under his direction. He has been superintendent from the opening of the works up to the present time. The great specialties of the works are making steel boiler-plate, carriage-spring steel, and a general variety for cutlery. The open-hearth steel manufactured there is largly used at the South Boston Rolling-Mills to make boiler-plates. There has been an increased demand for wire the past few years, on account of the new inventions in electricity. A project is on foot to establish a joint-stock company. The Norway Iron-Works have always been a paying concern, and it is not on account of any suspension the proprietors retire. The money volume of the business at the works has amounted to at least a million and a half of dollars yearly, and for labor alone seven thousand dollars have been paid out weekly. Six hundred men are at work, representing three thousand persons, and the suspension of the business at the present time would prove a very serious matter. There are great inducements to capitalists and men of enterprise to continue the business, considering the easy facilities for delivering the raw material to the wharves and the remov-

Digitized by Google

ing of the same when manufactured. For the last year, experiments have been going on to substitute petroleum instead of coal. Some furnaces have been reconstructed for the use of this material with every success.

The Centralia Mining and Manufacturing Company, Centralia, Ill., has placed its order with the Lechner Manufacturing Company, Columbus, Ohio, for roller chain belting. This company has also made shipments of steel roller chain to the Montgomery Iron-Works, Montgomery, Ala., for traction engines; D. Giles & Co., Chattanooga, Tenn.; and the Ohio Pipe Company, Columbus, Ohio, for racking carriage on lifting cranes.

The Brier Hill Iron and Coal Company is making preparations to engage in the manufacture of dephosphorized metal. The spiegeleisen furnace built by this company is rebuilding under plans prepared by Edward L. Ford, of Youngstown, Ohio. The metal while heated to a liquid state in the blast-furnace is carried to the new furnace in ladles, and subjected to a certain process that removes the phosphorus, leaving only the pure metal, which is a very valuable product. Work is pushed on the furnace, and, if the weather continues fair, it will be ready for operation in a few weeks.

The Martel furnace, Mich., has blown out for the winter. The cause is said to be the depressed state of the iron market.

The Penn Iron Company, of Lancaster, Pa., has given notice to its puddlers of a 10 per cent reduction to take effect December 15th. It is probable that the works will shut down, as the workmen refuse to accept the reduction.

The Union Rolling-Mill at Cleveland, O., was almost destroyed by fire December 9th. The loss on the building is $20,000, and on the machinery probably between $50,000 and $60,000. The insurance can not be estimated.

The Mount Hickory Rolling-Mills were destroyed by fire December 9th. The loss is estimated at $200,000; insurance, $90,000.

At a meeting of the Toronto City Council, it was decided to grant a lease of a portion of the marsh lands for the purpose of aiding in the establishment of iron and smelting-works, for the term of forty-two years, at a rental of $1 per acre per annum, and that the real estate, plant and machinery be exempt from taxation for ten years.

The Scranton Steel Company has given notice of an increase of capital stock from $600,000 to $1,500,000. It is said that it has received a big contract, and the increase was necessitated thereby.

The large rolling-mills of Coates & Brothers, George, W. P., and Charles E. Coates, at Locust Point, near Baltimore, Md., have suspended operations. The suspension is attributed to the recent heavy failures in other cities and to the great depression in the iron trade during the past two years. Their liabilities are $175,000; assets, from $40,000 to $100,000. The firm promises to pay every dollar of its indebtedness. Two hundred employés are thrown out of work. The mills were built in 1882.

The Dickon Manufacturing Company, of Scranton, Pa., has reduced wages 10 per cent.

The Coosa furnace, at Gadsden, Ala., was burned December 9th. The fire was caused by one of the gas-blowers exploding near the furnace-shield. The latter is a total wreck. The engine, boilers, and 400 car-loads of coke were also destroyed. The loss is nearly $150,000, with no insurance.

About seventy mechanics, who have been discharged on account of slackness in the work from locomotive-shops in Paterson, will sail for Europe, to go to work at iron steamship building on the Clyde.

The Phillipsburg sheet-iron mill, which is considered the largest manufactory of the kind in New Jersey, after one week's idleness, started up again with a reduction of 10 per cent in wages, making a total reduction in wages within a month of 15 per cent. Nearly all of the iron mills through the Delaware Valley are making a like reduction. An overstocked market is given as a cause. The owners of mills say there will be little work done this winter.

The contracts for the supply of metallic label cases and printed wooden tags for the use of the Post-Office Department have been awarded to Charles R. Penfield, of Lockport, N. Y., and Smith, Egge & Co., of Bridgeport, Conn.

Nineteen creditors of Brown, Bonnell & Co., by their attorney and by consent of Brown, Bonnell & Co., entered judgments in the Common Pleas Court December 10th to the amount of $142,000. Executions were issued, but nothing further will be done until after a hearing before Judges Welker and Baxter, at Toledo, on December 17th, on a motion to discharge Receiver Gayette Brown, of Cleveland.

The rail-mills of the Albany & Rensselaer Iron and Steel-Works at Troy, which employ 400 men when busy, have shut down. General Marvin says the condition of the labor market does not admit of the running of the mills at present. The iron and merchant steel-works were running, though not at full capacity. The combined works employ, at full capacity, 3000 hands. Less than half this number are now at work.

From Pittsburg, it is reported that the rail department of the Pittsburg Bessemer Steel-Works at Homestead have been shut down, throwing 800 men out of employment. Andrew Carnegie stated that the Edgar Thomson Works, at Braddock's, which employ 3000 men, would probably follow suit in a week. McKee, Anderson & Co.'s mill, at Beaver, Pa., has also been closed, and will remain closed until after the holidays. The Manchester Iron and Steel-Works will suspend operations on account of scarcity of stock, and 150 men will be thrown out of employment. The puddling department of Kloman's Superior Mill, which suspended four weeks ago, will resume.

The Electro Metal Refining Company of this city, says the Rome, N. Y., *Sentinel*, has been engaged since last May in putting in a plant at the malleable iron-works, for the purpose of treating base bullion by electricity, and separating the lead in the bullion from the impurities. Mr. N. S. Keith, of New York, after years of study, has discovered a new mode of doing this work by electricity. It has been tried on a small scale and has been found to work successfully.

A part of the malleable iron-works building which has heretofore been used as a molding-room has been partitioned off for the purpose of constructing this plant. In this room, have been built 30 circular vats or tanks. These vats are made of a composition as hard as rock and rest on a floor of the same substance. Each vat is six feet in diameter on the inside and 40 inches deep. There is a core two feet in diameter in the center of each vat, extending from the bottom to the top. In the center of each core is a copper conductor for carrying the electric current from one vat to the next one, and so on through the entire series of 30. There are but a few inches of space between the vats. Within each vat, are 13 cylinders of thin sheet-brass extending from the top of the vat down two feet. These brass cylinders are in a nest, two inches apart, and range from two to six feet in diameter. These cylinders are termed the cathodes. The bottoms of the cathodes rest on a copper conductor through which the electric current passes. This conductor passes under the bottom of the next vat and up through the center core to the top. The cathodes can be taken out of the vat, and put back again whenever it is necessary. A clear space of about a foot is left in the bottom of the vat.

Each vat is provided with what is called an anode frame, similar in construction to the cathodes, being a nest of brass bands two inches apart. These bands are, however, but two inches in width. In the center, is a copper hub, from which arms or spokes extend, like the spokes of a wagon-wheel. Into three of these spokes, are set copper conductors, and to the conductors are riveted the brass bands which form the frame. In the copper hub, is a socket which sets on to the copper conductor that comes up through the core in the center of the vat. To each of the brass bands are attached small brass hooks which look like the heads of large pins. The vats stand between three and four feet high on the floor, and each one is covered with a heavy movable wooden cover. When these covers are all down, they form a large platform or stage over the entire series of vats. The covers are taken off and the cathodes and anodes lifted out of the vats by means of a traveling crane.

The base bullion is melted in a reverberatory furnace. On a circular revolving pedestal, are twelve molds. The bullion is run into these molds and forms plates two feet long by six inches wide and one eighth of an inch in thickness, and provided with two ears or loops. By the time a casting makes one half the circuit after being poured, it is cool enough to be taken out. With one man to pour and another to remove the plates, the casting can be done very rapidly. After the plates are removed from the molds, they are inclosed in muslin bags and hung by the ears or loops on the pins with which the brass hoops of the anode frame is provided. These plates weigh about eight pounds each. After the frame is full or loaded with plates, it is lifted by the traveling crane and carried to any vat required and lowered so that the plates hang between the cylinders of brass in the vat, and the copper hub of the anode rests on the copper conductor in the core of the vat. After all is in readiness, a solution is let into the vats, and the electrical current is started by means of an Edison dynamo that is in the building. By means of the copper conductors, the current is conveyed from one vat to another; that is, the copper conductor in the core transfers it to the anode frame by means of the copper conductors in the arms. It passes through the solution, acts on the plates, and passes off on the copper conductor to the next vat, and so on around the whole thirty and back to the dynamo, forming a complete electrical circuit. It is intended to start three vats a day for ten days. At the end of that time, the whole thirty will be in operation, and the first three will be ready to clean up. If every thing works as is expected, three tons of pure lead will be taken out each day.

By means of a system of wooden pump-logs underlying the vats and communicating with each of them, the solution is forced into the vats from the bottom, overflows at the top, and is carried by conductors to a large cistern. Thence it is pumped up into an overhead tank situated higher than the vats, and from which the original supply comes. This tank is supplied with a copper steam coil, by means of which the solution is heated to about 100 degrees, when it overflows into pump logs by its own gravity and escapes into the vats to be used over again. This process proceeds uninterruptedly. By this means, a constant circulation of the solution and a uniform temperature are maintained. The solution is made of acetate of soda, sulphate of lead and water, and is kept at a density of about 10 degrees Baumé.

Power will be furnished by the malleable works engine, and the dynamo will make 1500 revolutions a minute.

The lead thus produced is pure, and can be used for purposes for which the article is in demand, such as white lead, paints, sugar of lead, and is especially adapted for the new system of storing electricity. This company has contracted all the lead it can manufacture to the American Storage Battery Company, at about $60 per ton above the quoted price of lead. The Electro Metal Refining Company has a capital of $100,000. The officers are as follows: President, N. S. Keith; Vice-President, Samuel Wardwell; Secretary and Treasurer, J. S. Wardwell. Among the directors are A. Ethridge, Edward Comstock, M. D. Barnett, C. O. Yale, and others.

GENERAL MINING NEWS.

ARIZONA.

PIMA COUNTY.

QUIJATOA.—J. W. Mackey and J. W. Flood, of San Francisco, have, it is rumored, purchased these mines. The sale was negotiated by W. Lytle, of the same place, who takes an interest with them. The price paid was $450,000. The mines are located eighty miles southwest of Tucson, and were discovered last May. The purchase was made on the report of J. N. Low, W. S. Patten, and Hank Smith, acknowledged to be the best authority on the coast. The purchasers will begin operations at once on an extensive scale, putting up the most approved machinery for developing and working the ore.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

BODIE CONSOLIDATED.—The official report for the week ended December 1st shows: Ore crushed, 120 tons; average pay value of pulp, $15.80 per ton; of tailings, $3.05. Bullion shipped, $6377.83.

STANDARD CONSOLIDATED.—For the same week, the report from this mine shows: Ore extracted and shipped to mills, 1419 tons; crude bullion received, 2346 ounces; bullion shipped, $16,324.50.

COLORADO.

BOULDER COUNTY.

Mr. J. R. Wood, of Boulder, sends us the following notes under date of the 5th: Owing to the continuance of the mild weather, mining in this county has not yet lost its summer impetus. Prospecting is still carried on upon the surface, as there is no frost in the ground where exposed for one or two hours during the day to the sun. The miners in the gulches upon Four Mile Creek are still doing some work, but expect to be closed down by cold any day. This gulch has been worked steadily for the past fourteen years, and a number of claims have paid handsomely. The work is necessarily slow, as, owing to the large amount of heavy boulders and lack of dump-room, a hydraulic can not be used. During the last two years, most of the work has been done by Chinamen under lease. As the cañon is narrow and is now occupied by the Greeley, Salt Lake & Pacific Railroad, a large amount of good ground can not be worked. Six miles from Boulder and one mile from the station at Crisman, are located the Yellow Pine mines, owned by Mr. George Williamson, by whose courtesy we were enabled to make a thorough examination, and were agreeably surprised at the showing of ore and the amount of development-work done. With the main working level at an altitude of only 7000 feet above the sea, the various tunnel-mouths one hundred feet above one another open into the hill-side, until, at the discovery-shaft, we are 800 feet above the lowest working, while the mountain still ascends at an angle of 45 degrees 300 feet higher, admitting all the work to be done through tunnels, shafting being only necessary for ventilation, and nowhere need more than 100 feet be sunk or raised to connect any two succeeding levels, thus doing away with all expensive machinery in handling rock or water. The property consists of the Yellow Pine, Volcleuse, Duroc, Gray Copper, and Mitchner lodes, and has been opened by 4955 feet of tunnels, connected by 912 feet of shafts. No stoping has been done to speak of, the owner's working plan being, "as long as the work of exploration pays for itself, no stoping will be done." In every tunnel, we found large blocks of ground from 100 to 200 feet long by 100 feet in hight, carrying a mineral streak of from one inch to five feet of ore, averaging 300 ounces of silver per ton, while the sorters were saving one grade as high as 800 ounces. The pay-streak in the Yellow Pine vein is from two to five feet in width. An average sample from the widest part gave 275 ounces. The ore apparently lies in a chimney whose dip is to the northwest, and as each succeeding tunnel has reached it, the ore-body maintains its quality and strength. The east wall, upon which the ore lies, is perpendicular, and wherever opened carries a regular northeast and southwest course, and as yet has shown no break. English, Welsh, and American miners with whom I have talked say they never before saw so fine a wall. Some cross-cutting has been done; but as yet the other wall has not been found, although bunches of ore and small feeders are encountered for thirty feet. Thirty men are steadily employed, and as the vein-matter is soft, a large amount of development is accomplished monthly. In the immediate neighborhood of the above mines, is the Five Brothers, a tellurium-bearing vein, which is worked by five men under the direction of Mr. E. McCormack. Not much ground has been opened yet, but the work has paid well as far as prese-

cuted. The Rob Roy, an extension claim upon the Yellow Pine vein, is worked through a cross-cut tunnel now in 100 feet. Another vein carrying a paying body of silver-bearing ore was cut at 80 feet, and is now opened by two headings from the tunnel, while the tunnel-breast is pushed by two shifts of men. The Neikirk concentration mill, at Crisman, after four years of continuous work, is undergoing preparations for putting in a new concentrator, the invention of a Boulder man. Although this machine has been at work in the county for about two months, and when seen by us appeared to be making a close saving of the mineral, still the operators could not be got to make a thorough test so as to ascertain the actual saving, appearing to be satisfied with what they could see. We hope that this may now be arrived at, as the cost of the machine is not more than $500, and the power used only one half horse, with a capacity of 15 tons daily. As the greatest want of the miners of Colorado is a concentrator having the requisites of economy in construction and power used with large capacity, we watch with deep interest any machine that promises to meet the conditions.

Work is steadily prosecuted on the Melvina lode by a force of 15 men. So far, it has been found necessary to employ the full force in replacing timber and putting the mine into shape for safe working, as the action of the water while standing idle had done a large amount of damage, the walls being soft. Enough ore was found in the old workings to nearly cover the expense, and new ground is now opening.

The concentration-works of the Century Company, at the mouth of Gold Run, continue steadily at work, treating 15 tons a day. The company is putting in tables to amalgamate the ore before it goes to the concentrators. The record shows a saving of 97 per cent upon some ores, with an average of 85 per cent. Work is about to be resumed on the Hoosier Tunnel. As this is a strong vein, some 60 feet wide, which has paid at times, it is expected that further explorations will open another ore-body.

The Victoria lessees are about purchasing a No. 8 Cameron pump, and on its arrival will sink the main shaft 200 feet deeper. In doing the annual work upon the Valley Forge, a body of ore giving mill-runs of 2000, 3000, and 4000 ounces was encountered. But for some reason, the mine immediately closed down. As this was done before the extent of the ore had been determined, the trouble is not in the vein.

CLEAR CREEK COUNTY.

PAY ROCK.—During the past two weeks, the superintendent has put 65 new lessees at work on the Pay Rock, in addition to the large force previously employed. The pumping out of the shaft below the tunnel level has opened up again for mining 1000 feet of levels, which will be rapidly extended. Two pumps, a sinking and a No. 5 Knowles, were used in cleaning out this shaft. The old stull timbers kept their place well. In No. 3 level, a scale caved off one side, disclosing about four inches of 600 or 700-ounce stuff and 15 inches of ore running from 70 to 80 ounces. Larger masses of ore are now to be seen in the mine. Its output this winter promises to be much increased.

DOLORES COUNTY.

PHŒNIX.—Some more fine ore has been found. It is not a new body of ore, but is merely a continuation of the mineral on which they have been working. It is bromide in character, and it is thought the whole body will run high. Tests made have run very high.

GUNNISON COUNTY.

Gunnison City is enthusiastic over the prospect of several new smelting establishments to be built in that vicinity early next year. Mr. S. D. Patrick left Denver for Alma to superintend the removal of the Stevens furnace from that section to Gunnison City. The Stevens process has not had success in Colorado thus far, although it is claimed to have worked in a satisfactory manner in Utah and Omaha under thorough test.

The mines at Spring Creek are fully meeting all expectations, and a number of good producing properties have been opened during the past year.

The Von Cota lode, located only last June, by a limited amount of exploration-work disclosed three and a half feet of lead carbonate ore, containing fifty-two per cent of lead and twenty-two and a half ounces of silver to the ton.

The James lode shows a fair body of ore, carrying sixteen ounces in silver and from forty to fifty per cent in lead. The mine is located on the south end of Bald Mountain.

The Boston lode, on Ute Mountain, is owned by a number of Leadville gentlemen. The workings expose quite an ore-body running seven ounces in silver and seventy per cent in lead.

Excellent ore-bodies have also been opened along Ohio Creek and the White Pine District, the mines of which are owned principally by Leadville gentlemen.

The Doctor mine is shipping regularly to the smelting-works near Salt Lake City, a distance of 460 miles.

HINSDALE COUNTY.

HOTCHKISS.—The tellurium streak in the formerly famous Hotchkiss mine, the riches of which led to the establishing of Lake City, has been struck again, after years of idleness and litigation. The mine was re-located as the Golden Fleece, and is owned and patented by Samuel Wendel and George Wilson. A contract had been let to extend the lower drift, and work had just been commenced when at 240 feet the ore-body was struck. It extends from top to bottom in the face of a drift, and is improving at every shot. The ore-body is a foot in width, with tellurium and petzite freely interspersed.

LAKE COUNTY.

ÆTNA.—The lessees of this mine on Carbonate Hill have begun hoisting mineral. They have between $9000 and $10,000 worth of ore broken and ready to fill into the bucket, with assays from the different stopes ranging from 37 to 400 ounces per ton.

CHRYSOLITE.—Drifting to the south and east from the All Right No. 2 shaft is advancing at a satisfactory pace. The south drift will soon be connected with the Kit Carson No. 2 shaft, and thence will be continued to the Eva No. 5, which is already connected with the principal workings of the mine. The driving of the Iron incline is also making good progress. Work on the Chrysolite No. 6 shaft will begin soon. It is situated back of the office buildings. This shaft was begun by W. S. Keyes, while manager of the property, several years ago. The shaft has a depth of 152 feet.

CROWN POINT.—Exploration and development-work at this mine, on Rock Hill, has been advancing very satisfactorily. The extension of the underground workings of the mine broke into the drift of the La Plata mine, on the territory of the Pinnacle lode. In driving this work, a large body of ore was opened, running twenty-five ounces in silver and thirty-five per cent in lead. The extraction of ore and shipments in large quantities will begin at once. The hoisting-plant that is being placed on the Crown Point shaft, a new shaft-house, ore-bins, and other surface improvements are also under way.

FREYER HILL.—Only three furnaces are in blast at these smelting-works. Several of the old furnaces at this establishment have been torn down, and will not be rebuilt until next spring.

GRIFFIN.—This property is in the new mining district on the west side of Tennessee Park, about six miles from Leadville. A shaft has been sunk about sixty feet. It is entirely in mineral, and is daily yielding a considerable amount of ore, which is shipped to the Arkansas Valley smelter. The ore consists of quartz, galena, zinc-blende, and possibly some antimony. The silver occurs as sulphurets, and pieces of ore are frequently met very rich in the latter mineral.

IRON SILVER.—A small force of men is again at work on the plant at the Moyer shaft, preparing for the resumption of work on the shaft.

LA PLATA.—All five of the furnaces are in blast.

LITTLE CHIEF.—This mine, although closed down during the first ten days of November, made shipments during the month of 150 tons of ore. Owing to repairs to machinery and the performance of considerable unproductive exploration-work, the operations of the month have resulted in yielding barely enough to pay the unusual expenses, and no profit was derived for November's work.

MORNING STAR.—A four-foot body of ore is exposed in the Kitchen shaft of this mine, which it is calculated will run from $200 to $300 a ton.

ROBERT E. LEE.—This company has recently taken over ten thousand dollars from supposed barren ground in the vicinity of the south shaft.

ST. LOUIS.—The output of this mine, formerly the Miner Boy and Colorado Prince mines, during November amounted to 500 tons of ore. The average value of the ore is about one and a half ounces in gold to the ton, and fifteen ounces in silver. The ore is extracted from a strong vein opened on the line of the Colorado Prince tunnel, about 500 feet from its entrance. During the past week, a seam of ore eighteen inches in width has been discovered that will run ten ounces in gold to the ton and seventy-five ounces in silver. During the past few days, boilers, steam-pumps, and hoisting machinery have been purchased by the lessees, and preparations are making to develop the vein below the tunnel level.

PITKIN COUNTY.

The smelter at Aspen has shut down, and will not start up again until there is a certainty of buying ore in quantities to warrant the expense of running.

SUMMIT COUNTY.

ROBINSON.—Mr. Greer, the lessee, reports shipping ore at the rate of about one hundred cars a month. The ore-body in the lower levels is stated to show a marked improvement.

DAKOTA.

FATHER DE SMET.—The superintendent's report for nine days ended November 30th shows: Ore extracted from first level, 1500 tons; second level, 800 tons; third level, 400 tons. Ore milled, 2700 tons. Golden Gate south header, third level, advanced 13 feet.

STAND BY.—The twenty-stamp mill, recently started up, works smoothly, and the mine is showing up well.

IDAHO.

BALTIMORE & VICTORIA.—The Baltimore, Victoria, Minnie May, Cumberland, and Ida Harland lodes and the Baltimore mill site—all situated in Warm Springs Creek Mining District, Alturas County—are to be worked by this company, recently organized at Salt Lake City with a capital stock of $1,500,000.

KENTUCK.—For the purpose of carrying on a "great mining business," this company has been organized with a capital stock of one million dollars. The property proposed to be operated is situated in Mineral Hill Mining District in the county of Lemhi, and consists of the Kentuck and the Lost Miner lodes.

MICHIGAN.

The product of the mines mentioned for the month of November is reported in tons as follows:

Calumet & Hecla	1757	Copper Falls	59
Quincy	452	Pewabic	45
Franklin	201	Portage	40
Atlantic	168	Wolverine	40
Allouez	100	Hancock	34
Huron	73		

CONGLOMERATE.—One head of Ball's stamps in the new mill of this mine, at Lac la Belle, started up some three weeks ago and is working very satisfactorily.

HURON.—The directors have levied an assessment of one dollar per share. The Houghton *Mining Gazette* says: The decided improvement in the lode in various parts of the mine, which the last two monthly products, 70 and 73 tons respectively, corroborate, fully warrants the management in erecting another head of Ball's stamps, which will admit of the mine doubling its present handsome product and assuming a position to earn something for its stockholders. To make this much needed addition to the mineral crushing plant, this last assessment is called, which will be ample, we are informed, to pay for the new machinery and the other expenses on the mine incident to its dressing-works' enlargement.

IRON STAR.—This new corporation has been recently organized by Detroit and Lansing parties, principal among which are James M. Turner and John S. Newberry. Capital stock, $500,000, with $5000 actually paid in. It is not stated exactly where the new company proposes to operate, but presumably the Agogebic District will be its field.

ROPES.—The official report shows that a clean-up of all the rock treated—272 tons—had just been finished. The following facts are given:

Gold from mill	$1,323.02	
Gold from concentrates	328.14	$1,651.16
Silver (native) from mill	166.01	
Silver from concentrates	192.80	358.81
Total gold and silver		$2,009.97

The records kept at the mill show that the ore fluctuated considerably in value. The first lot milled was from a shaft sunk to a depth of 25 feet, the upper portion giving a mill result of $6 or $7 per ton, the lower portion, from $14 to $15. The third test of ore treated was 150 tons from drifts run at a depth of 25 feet and a continuation of the shaft downward, which yielded about $6 per ton. At a depth of 30 feet, a dike of greenstone was encountered, both in the drift and the shaft, breaking up the lode and forming fully 50 per cent of it. The 150 tons was composed of this mixed matrix. It was subsequently found that the drift and shaft were entirely off the lode, a cross-cut to the south of a few feet from the bottom of the shaft, which was down 45 feet, revealing it in its full width and richness, and a like cross-cut in the same direction from the end of the drift, 20 feet from the shaft, also found in all its former richness and strength. This fact shows plainly why the yield of gold and silver was not greater. The fourth lot milled was 22 tons of siliceous talcose slate from an opening 100 feet east of the Curry shaft, where a belt of this slate 8 feet thick lies between two quartz lodes each 4 feet thick on the north and south of it. A shaft was sunk 14 feet and the belt cut across, as well as the two quartz-veins. From this run, per ton of rock, $3 at the mill and $2.50 from the concentrates were obtained. It was the purpose of the management to have milled a quantity of ore from the north lode, as it runs much higher in gold than the other openings, with but little silver, but the arrival of cold weather prevented. Examination of the tailings taken from the plates and concentrator give from $6 to $9 in gold and from $2 to $3 in silver, per ton. Two assays of 50 pounds of the tailings, after the run, showed, respectively, gold, $18; silver, $2.24; and gold, $15; and silver, $19 per ton. This great discrepancy shows that amalgam has gone over from the mill and is the cause of it. The results as shown give a value of over $20 per ton on the ore as it was run, and it is expected on the resumption of mill work that certain appliances will be brought into requisition which will reclaim that portion which has heretofore been lost. Fraser & Chalmers, the mill builders, have the matter now in hand, and are confident they can quickly remedy the difficulty.

Digitized by Google

During the last ten days of work, the developments made did more in proving the width and richness of the lode than all that had been performed previous to that time. The trial, even with its numerous drawbacks, can not be looked upon as other than a most favorable one, and the management, together with those familiar with the mine's showing, are confident that the success of the enterprise is already well assured, and that a renewal of operations will be met with results fully up to the standard as set by the most sanguine friends of the enterprise.

TAMARACK.—The sinking of the big combination shaft continues. At present, a depth of 1100 feet has been attained.

MONTANA.

BEAVER HEAD COUNTY.

HECLA CONSOLIDATED.—Another furnace is to be added to the smelting-plant of this company at Glendale, increasing the capacity of the works to 150 tons a day. The Hecla Company, it is reported, is turning out more and better ore from its mines on Lion Mountain than it has done before since its organization.

SILVER BOW COUNTY.

GAMBLER.—It is stated by the Butte *Inter-Mountain* that this claim was lately bought for $1500, and sold to the Montana Copper Company for $8500.

NEPTUNE.—This mine, owned by Mr. Clark, is opening and is producing six tons of ore daily, which is worked in the Moulton mill, and pulps an average of $76.

POLLOCK.—This mine, located east of the Poser and also owned by Mr. Clark, is producing eight tons of ore daily. The last shipment of ore made to the Moulton mill returned $101 per ton.

NEVADA.

EUREKA COUNTY.

EUREKA TUNNEL.—The ore on the Eureka Tunnel dump at the time of attach ment has been sampled and settled for at the Eureka Consolidated furnace with the following results: The sacked ore assayed $574 per ton, silver; No. 1 hard ore, $97, the screenings from which went $46, and the carbonate ore, $59; this last carrying $20 in gold. We are informed that after payment of the Hansen claim and costs, amounting to $476, the yield of this ore, thirteen and a half tons, will be paid on the company's indebtedness. Including this lot, which was taken out of the mine in September, the yield for that month was $6594.23 net to the company.

LINCOLN COUNTY.

. DAY.—Work in the mines of this company is steadily pushed ahead. Ore is extracted and shipped to the furnace daily. The mines are at present working a larger force of men than they have for months. The furnace is getting into the best of order at Bristol. The indications are, that it will make a steady run of several months when it starts, which will be about the first of the year.

STOREY COUNTY—COMSTOCK LODE.

At the middle mines, prospecting is pretty much at a stand. In the Chollar and Potosi, no attempt has been made to prospect in a long time. At the Savage they tried it for a long time on the 2700 level, but found themselves headed off in every direction by water, so were obliged to return to the main incline and put in the time at sinking that, until the new hydraulic pump shall make it safe for them to cross-cut in the wet ground above.

At Gold Hill, the Yellow Jacket, Crown Point, and Belcher companies are taking out all the ore that mills on the Carson River can reduce with the present stage of water.

The Alta folks have drained their mine nearly to the 2150 level.

John W. Mackey, who has just returned from a thorough examination of the Comstock mines, while declining a newspaper interview, according to San Francisco papers, apparently wishes it to be understood that his faith in the productiveness of the mines is undiminished. He says that, just as soon as the water can be got out of the lower levels, the public will be astonished at the richness of the remaining deposits. He has ventured no opinion when the water will be exhausted.

MEXICAN.—At the recent stockholders' meeting, held in San Francisco, the following report of work done in the mine for the fiscal year ended November 30th, 1883, was submitted: There have been extracted during the year 94 tons of ore; there have been milled 308 1340-2000 tons, yielding $3929.23, or at the rate of $12.72 per ton, this being the yield of the ore-streak found on the 2700 level near our north line. There have also been extracted from the mine in the work of exploration 4019 tons of waste rock. No work has been done during the past year on the 1600, 2000, 2360, 2500 and 2700 levels, except the necessary repairs to the various drifts and winzes used for drainage and ventilation. At the 2000 and 3100 levels, work was continued. The Sierra Nevada, Mexican, and Union shaft has not been sunk to any great depth during the past year, the work being confined to necessary repairs. In January last, the 14-inch pumps that had been used in the shaft were taken out and 17-inch pumps substituted therefor, thereby increasing the pumping capacity about 50 per cent and enabling the shaft to handle all the water from the Sierra Nevada, Mexican, and Union Consolidated mines without any trouble. By the use of the diamond drill, I have avoided or controlled the influx of large bodies of water, the amount of water in the aggregate being less at this date than twelve months ago. As some increase of water is always found in opening up new levels in depth, this fact proves a material decrease of water in the levels above the 2700, and indicates a further decrease during the next year. Although the ore discovered on the 2700 level, near our north line, proved of no great extent or value, the development of the low-grade ore in the 3100 west cross-cut, as before described, which is probably the same vein in which the joint Ophir-Mexican winze from the 2900 to the 3100 was sunk, gives renewed hope that further explorations may find something of value.

The financial statement shows:

Balance from last year	$69.92
From other mines	514.50
From San Francisco office, sundry drafts on president	289,869.36
Total	$290,453.78

DISBURSEMENTS.

Salaries and wages	$89,981.68
Supplies and miscellaneous expenses	109,349.34
Sierra Nevada, Mexican & Union Shaft Company	86,558.13
Legal expense	416 66
Exchange	1,437.00
Milling	2,469.36
Royalty on ore	154.37
Gross expense	$290,366.51
Balance cash on hand	87.27
	$290.453.78

NEW MEXICO.

SAN PEDRO.—A dispatch from Boston says that the bondholders of this company have voted to foreclose its mortgage and reorganize by issuing new stock to its holders. Fifty per cent of its mortgage is to be canceled, and for the remainder preferred stock at $10 per share is to be given. Each bond is to contribute $25 in cash. The claim of G. W. Ballou & Co. against the company, amounting to $240,000, is to be reduced to $200,000, and payment made in preferred stock.

PENNSYLVANIA.

Mr. John Eyerman, of Easton, Pa., sends us the following:

THE FRIEDENSVILLE ZINC MINES.—After a number of years of idleness, work has again begun at the old Ueberroth mine, formerly owned by the Lehigh Zinc Company, but now owned by Messrs. Osgood & Co., of New York City. Four boilers (out of sixteen, which were used to run the large West engine) are in operation. They supply steam for two donkey-pumps that are used in attempting to empty the mine of a great body of water. They have been working three weeks, and about ten feet of water have been pumped out in this time. No doubt the large engine will be used, as it will take months to pump the mine dry with the two donkeys. The surface opening of the mine is 465 feet in length by 435 feet in width. It is said that the mine is 250 feet deep. The water is now about 49 feet from the surface, making about 200 feet of the mine still under water. The bottom was reached by an inclined plane, besides several shafts. The engine-shaft at the West engine is 35 feet by 24 feet. The diameter of each of the two pipes is 36 inches. Each walking-beam of the engine weighs 48,000 pounds, and it is stated that it required 40 head of horses to convey it from Bethlehem, three miles distant. The cylinder is 110 inches in diameter, and has a ten-foot stroke. The engine can raise 12,000 gallons of water 300 feet in one minute. Besides this large engine, there is a smaller one, just opposite, on the other side of the mine opening. The shaft is 18 by 15 feet. When these two engines were working, all the wells, for miles around the country, were dry, and the Saucon Creek a large river.

As the ore (calamine, smithsonite, and sphalerite) in this mine is near the surface, it is not, at present, difficult to work. The calamine is found in large quantities disseminated through the limestone. It is found mostly on the north side of the mine, where it is worked by a small force of men.

This mine has furnished, and will continue to furnish, the finest specimens of calamine (or silicate of zinc) known to the world. It is very often found in botryoidal and stalactical forms. It is not seldom that sheets or plates of calamine from two to three feet square and from one eighth to one fourth of an inch thick, and containing thousands of little crystals on the surface, are found between the crevices of the limestone. Again, it is found as a thin coating to the inside of a quartz geode. This ore is quite scarce at the Endy mine. It seems to have been replaced by the blende. The smithsonite or carbonate of zinc is found in white scales and in granular masses, coating calamine and blende. It is also more commonly found as a brownish earth, which hardens when dry. It is found near the center and along the west side of the mine. It has often been mistaken for clay. This is also mined at present by a small number of men. The sphalerite or zinc-blende is not mined. It is found throughout the mine, with pyrite disseminated through it. It is not met with in as large quantities here as at the Endy mine. Greenockite (sulphide of cadmium), hydrozincite, and goslarite (sulphate of zinc) are met with in smaller quantities. The sulphate of zinc is scarcely ever found. A considerable quantity of greenockite has been mined. It is found as a yellowish powder coating blende and limestone. It was formerly separated at the Bethlehem works.

The ore is conveyed in wagons from the mines to a wharf on the Saucon Iron Company's siding, about two miles from Bingen, on the Philadelphia & Reading Railroad. From this point it is forwarded to Bergen Point, N. J.

Zinc is reported to have been discovered in Lehigh County, at Coplay, and on a farm near Shinersville.

The Ueberroth mine was opened about 1850. The first person to announce the mineral was the well-known mineralogist, the late Prof. William Th. Roepper, of Bethlehem. He had strolled, one Sunday, through the farm of Jacob Ueberroth, and, finding several specimens of a crystallized substance, took them home, and afterward pronounced them to be calamine. His discovery led to the opening of the great zinc mines. Until the company failed, the ore was conveyed to the Bethlehem works. This company now obtains its ore (zincite and willemite) from Franklin Furnace, Sussex County, N. J. Works for the production of zinc oxide were built at Bethlehem about 1853. The Lehigh Zinc Company now owns a mine (producing zinc and lead) near Landisville, on the Pennsylvania Railroad, in Lancaster County, Pa. It is known as the Bamford zinc mine.

UTAH.

The bullion shipments made to Salt Lake City during the eleven months of this year amounted to $6,326,780. This assures a yield considerably in excess of that of any previous year, inasmuch as several steady producers are not reported in these weekly statements. The values, too, are fixed at local rates.

JUAB COUNTY.

WAR EAGLE.—A contract has been let to run a 186-foot tunnel on this mine. There is a tunnel of 130 feet in length already on the claim, and, with the 186 feet additional, the owners hope to tap the vein.

SALT LAKE COUNTY.

GERMANIA.—The Germania Lead-Works are now building a large structure, which will be completed in about a month, says the Salt Lake *Tribune*, for the purpose of increasing the manufacturing facilities. The company purposes manufacturing all of the products from the smelters into every conceivable article that can be made from lead. The company will begin refining bullion immediately, no work of that kind having been done at the works for at least a year past. Hereafter, but little if any bullion will be shipped East, as the company in doing its own refining and utilizing its lead can dispense with these shipments. The gold and silver will be sent to New York. The works now produce about fifteen or twenty tons of bullion daily, aggregating about $2000 in silver and gold and about $1000 in refined lead. Out of this lead, there will be manufactured, when the works are completed, lead pipes, white lead, red lead, granulated lead, test lead, litharge, solder, Babbitt metal, and also all colors that are used in paints. The company has recently erected a fine sampling-mill, where all of the sampling of ores bought from the different mines is done. There are no such works nearer than Omaha and San Francisco. The Germania works will be so perfect that the company will be able to take the ore from the mines, sample it, smelt it, refine it, and manufacture the lead into almost any article for which that metal is used. The company is shipping constantly large consignments of white lead, in the shape of pipe, and is supplying a greater part of the territory. About 100 men are employed, and when the additions are completed and the machinery erected, there will be work enough for 150 men. Three assessments have recently been levied, aggregating $40 per share. This will make the capital stock $500,000, full-paid. With the present increase in the business, there is no doubt but that the capital stock will be increased to $1,000,000.

SUMMIT COUNTY.

BALTIMORE.—The company is running a drift at its mine on Connor Hill. It is driving through solid rock. The tunnel is now 450 feet long, with very good indications.

TOOELE COUNTY.

COLUMBIA.—This company has recently been organized with a capital stock of $500,000 for the purpose of carrying on mining and tunneling, and business operations on the General Hancock, the Grampian, the Hughes, the King Philip, and the Powell lodes, in the Columbia Mining District.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Dec. 14.

The mining market this week presents but few items of interest. While the aggregate number of dealings exceeds that of last week, they were not characteristic of any new or important features. Northern Belle continues to decline, and to-day was quoted at its lowest price on this market. Iron Silver was in great demand, and regained its former strength, being held firmly throughout. Sonora was very actively dealt in and was a little weak. Amie was actively sold and was also weak. Eastern Oregon suffered a strong decline, and was not so largely dealt in as usual. A complete summary of the market is given below. The total number of shares sold aggregates 120,260, as against 110,538 last week.

The Comstock shares were quiet and were generally weak. California sold from 28@21c., with a small business. Consolidated Virginia was fairly dealt in at irregular prices; it sold from 40@31@34c. Sierra Nevada was weak, under a small business, selling from $3.70@$3.05@$3.40. Union Consolidated was also weak, selling from $3.45@$3@$3.05. Mexican sold from $2.60@$2.10. Ophir was strong under a small business, selling at $7. Hale & Norcross sold at $1.75. Sutro Tunnel was quiet and steady, selling from 15@16c.

The Leadville stocks were actively dealt in at about steady prices. Amie was irregular, with a very active business, selling from 12@9@10c. Chrysolite was quiet and a little weak; it sold from $1.35@$1.25@$1.30. Dunkin was steady, with a small business, selling from 26@28@27c. Breece sold at 16c. Iron Silver was strong, under a very active business; it sold from $1.85@$2 10, the transactions aggregating 14,350 shares. Leadville was strong, with a fair business, selling from 40@50@49c. Little Chief was quiet and steady, selling at 56c. Climax sold at 7c.

The Bodie stocks were quiet and steady. Bodie Consolidated sold at 70c. Standard was quiet and irregular, selling from $6@$5.75@$5.88. Bulwer was moderately dealt in at steady prices, selling from 40@45c. Goodshaw sold at 16c.

The Tuscarora stocks were very quiet and were steady. Grand Prize sold at 28c. to-day. Argenta was quiet at 10c. Belle Isle sold at 20c. Navajo was quiet and steady from $3.20@$3.25. Independente sold at 10c., under a small business. Elko Consolidated was quiet and steady, selling at 19@18c.

In the miscellaneous list, Alice was strong, under a small business, selling from $2.50@$2.80@$2.70. Green Mountain was moderately dealt in at irregular prices; it sold from $1.20@$1.10@$1.15. Horn-Silver was a little weak under moderate transactions, selling from $6.50@$6. Northern Belle continues to decline; it sold from 45@20@22c. under moderate dealings. Robinson Consolidated was quiet and irregular, selling from 30@34@32c. Sierra Grande was steady at 66@64@65c., with a small business. Silver King was strong, selling at $7.25.

Barcelona was quiet and a little weak, selling from 23@20c. Central Arizona sold from 24@20c., under a small business. Decatur was moderately dealt in at steady prices, selling at 4c. Durango sold at 8c. Eastern Oregon was quite weak under a small business; it sold from 44@14@16c. Harlem was moderately dealt in at irregular prices; it sold from $1.20@$1.10@$1.15. Sonora Consolidated was very active at irregular prices; it sold from 26@22@23c. North Mexican was quiet and strong, selling from 51@65c. Colorado Central sold from 40@35@39c., under a small business.

MEETINGS.

The Alice Gold and Silver Mining Company, Walker Brothers' Bank, Salt Lake City, Utah. Annual meeting of stockholders and election of trustees, January 14th, between ten o'clock A.M. and five o'clock P.M.

The Colorado Central Consolidated Mining Company, No. 25 William street, New York City. At the recent meeting of the Board of Trustees, the following trustees were elected officers of the company for the ensuing year: President, Paul Lichtenstein; Vice-President, Herm. R. Baltzer; Secretary, Paul O. d'Esterhazy; Treasurer, R. V. Martinsen; Superintendent, at Georgetown, Colorado, George W. Hall.

The Gold Cliff Gold Mining Company, No. 46 Cliff street, New York City. Annual meeting of stockholders and election of trustees, December 22d, at one o'clock P.M.

The Grand Central Mining Company, Youngstown, Ohio. Annual meeting of stockholders and election of trustees, January 15th, at eleven o'clock A.M.

The Lake Huron Silver and Copper Mining Company, North British and Mercantile Insurance Buildings, St. François Xavier street, Montreal, Canada. Annual meeting of stockholders and election of trustees, third Wednesday in January next, at one o'clock P.M.

The San Juan & New York Mining and Smelting Company, No. 70 Broadway, office of Spencer, Trask & Co., New York City. Annual meeting of stockholders and election of trustees, January 22d, at three o'clock P.M.

DIVIDENDS.

The Homestake Gold Mining Company, of Dakota, has declared its sixty-fourth dividend of $25,000, payable at the office of the transfer-agents, Lounsbery & Haggin, Mills Building, No. 19 Broad street, on the 26th. Transfers close on the 20th. Total dividends to date, $2,287,500.

The Mount Pleasant Mining Company, of California, has declared a dividend (No. 4) of twenty cents per share, or $30,000, payable December 15th.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway, report as follows:

The week has been a dull one. Friday morning last, the market touched $1.18, but was rapidly advanced to $1.17⅝, Saturday afternoon. Monday, it opened at $1.16½; and during the present week, it has gravitated between $1.18⅝ and $1.16. Meantime, the price of refined oil has advanced from 9@9¼c., and is now 9½c. bid. From the best information we get from refined oil men, the export trade for the past three months has been the dullest for any similar period for years. The visible supply in seven European ports is about the same, perhaps a little more, than this time last year; but there has been no year since 1875 when there has been so little refined oil contracted for, for future delivery, as now. Last year, there were about one million barrels more of contracts held by the foreign trade than at present. Low prices have prevailed in Europe this fall; but when their present supply is exhausted, they will become buyers, and as the refined interests, Standard, Tidewater, and others, are now united in action and interest, they can fix the price of refined at a figure that will be remunerative, and higher prices for refined may be expected.

There has been a great deal of discussion during the week in both the New York Mining Stock and National Petroleum Exchange and the New York Petroleum Exchange on the proposed consolidation of the two. In each, there is opposition on the part of a minority; but the prevailing sentiment seems to favor a union of forces, and the establishment of one strong institution. It is believed that the question of consolidation on each Exchange will be voted upon, on the 22d inst.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Dec. 8	$1.16¼	$1.17⅛	$1.16⅛	$1.16⅛	5,223,000
10	1.16⅝	1.16⅝	1.15⅝	1.15¾	7,379,000
11	1.16	1.16	1.14	1.14⅛	7,158,000
12	1.14¼	1.15	1.13⅝	1.14⅞	7,238,000
13	1.15⅛	1.15¼	1.13⅞	1.14	5,199,000
14	1.13⅝	1.14⅝	1.13½	1.14⅛	4,698,000
Total sales					36,895,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, December 13.

There is no improvement in the market the past week, and prices drag along with only slight variations, except for Quincy Mining Company, which shows a decline from $52@$49¾. Calumet & Hecla was quite firm during the week at $239½, until to-day, when it touched $239. Franklin, after selling at $12 last week, declined on small lots to $11¾, a round hundred being taken at $11⅞. There were no dealings in the other stocks on the list, there being not the slightest disposition to buy or sell for speculative account. The condition of the ingot copper market does not warrant any expectation of a rise in that direction, and consequently we may look for a dull market for some time to come.

There was a little more activity in the silver stocks but not enough to indicate a boom in this class, for the present, at least. Bonanza sold at $1 7/16, a decline of $\frac{1}{16}$. Harshaw, 50c. Crescent, 15c. San Pedro awoke from a long sleep, and sold at 12½@15c. Sullivan sold at 89@90c. at the regular Board, and as high as 94c. at the Mining Exchange. Silver Islet declined from $8, sales, last week, to $2½, and rallied again to $3.

At the Mining Exchange, some considerable activity has developed in Empire, and all the lots for sale at 25c. have been readily taken. This stock has always been rather a Boston favorite, and we should not be surprised to see it resume its old-time activity. Bowman was quite steady at about 14c. until to-day, when it declined again to 12c. Dunkin is in fair demand at 27@29c.

BULLION MARKET.

NEW YORK, Friday Evening, Dec. 14.

The silver market abroad has been weaker, under a diminished demand for India exchange; and here, it has been affected in addition by a lower rate for sterling exchange.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
Dec. 8	50 13-16	110⅜	Dec. 12	50 13-16	110⅜
10	50 13-16	110⅜	13	50⅝	110⅛
11	50 13-16	110⅜	14	50 13-16	110⅛

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended December 14th, as compiled from various sources, amounted to $207,878, as against $288,000 reported for the previous week. The receipts from January 1st, 1883, to date are $11,026,321.

Foreign Bank Statement.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 3 per cent. During the week, the bank gained £193,000 bullion, and the proportion of its reserve to its liabilities was raised from 42¼ to 43⅞ per cent, against 41⅝ per cent at this date last year. The weekly statement of the Bank of France shows a decrease of 2,308,000 francs gold and a loss of 4,480,000 francs silver.

Ten-Cent Coin for Hawaii.—The superintendent of the Mint at Philadelphia has been notified that the Hawaiian government desires to substitute a ten-cent silver coin for the twelve and a half cent piece origi-

Digitized by Google

nally ordered, and has been granted authority to prepare a die in accordance.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14½ per cent, to arrive at actual value.

MINES.	States.	Month of November.	Year from Jan. 1st, 1883.

METALS.

NEW YORK, Friday Evening, Dec. 14.

Copper.—Business is very quiet, transactions being on a limited scale, with Lake at 14⅛@15c., Common outside brands, 14@14¼c., and the best of this class 14⅛@14¾c. Consumption appears to be fairly good, but we are approaching the end of the year, a time when manufacturers do not care to increase supplies of raw material. London is again lower, Chili Bars being cabled £57 10s., and Best Selected, £65. In spite of this decline, there are some inquiries at hand from abroad.

Tin.—There has been a bad break in this metal in London and here, due, it is said, largely to the increase in the production in the Straits settlements. According to dispatches to the Metal Exchange, London dropped from £84 on Wednesday to £83 on Thursday, and fell to-day to £82 10s. Here, spot Straits is 18⅝@18½c., with futures as low as 18¼c.

Lead.—Except a retail business in car-load lots, absolutely nothing has been done. Nominally, quotations are 3·60c., that figure being the one that it might be possible to get lead for, though for the time being there is little of it in the market. There is, however, no confidence in the metal, and there are few who would venture to advance any arguments in favor of an improvement.

Messrs. John Wahl & Co., of St. Louis, wire us as follows:

Our market is a little easier. Sales during the week aggregate 250 tons of Refined at 3·30c. Common lead is nominally the same as Soft lead.

Messrs. Everett & Post wire us as follows from Chicago:

Common and Refined lead are salable at 3·35c. Offerings are only moderate.

Spelter.—The dullness still continues at unchanged quotations, which are 4⅝@4½c. for Common Domestic.

Antimony.—Unchanged at 10½c. for Hallett's and 11½c. for Cookson's.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Dec. 14.

Mr. Edward J. Shriver, Secretary of the Metal Exchange, has published the following returns from 137 furnaces, of which 61 are in blast and 76 out of blast:

All grades.	Unsold stocks. Nov. 1.	Dec. 1.
Anthracite	24,599	16,063
Bituminous	38,078	39,976
Charcoal	38,520	39,787
Grand total	101,197	95,826

	Production. In Oct.	In Nov.
Anthracite	12,786	13,442
bituminous	36,829	37,883
Charcoal	6,319	6,102
Grand total	55,934	57,427

American Pig.—The market is quiet, transactions being limited to small lots to cover urgent necessities. There are frequent reports of sales at low figures; but they are so generally accompanied by exceptional circumstances that they can not be looked upon as representing average quotations. We hear of a sale of 5000 tons of Colebrook forge iron reported as having been sold at $17, delivered at works near the furnace. We quote Foundry No. 1, $20@$22.50, ordinary to choice; No. 2, $18.50@$19.50; and Gray Forge, $17@$19, all at tide-water. There have been some transactions in Bessemer pig at private terms. It has been a mystery how steel-makers could afford to pay the nominal figures hitherto current. Spiegel is dull, so far as actual transactions in the higher grade are concerned. We quote, nominally, $29@$29.50, with the market in buyers' favor.

At the Exchange, not a single transaction was reported during the week.

Scotch Pig.—The market is very dull and quiet, transactions being limited to small lots.

We quote ex ship and to arrive: Coltness, $22@$23; Langloan, $22.75@$23; Summerlee, $22.50; Eglinton, $20@$20.50; Glengarnock, $21.50@$22; Dalmellington, $20@$21.

Warrants at the Exchange to-day were 44s. 2d.

Steel Rails.—From four different quarters come reports that indicate a further weakening of the market. In Chicago, rails have been offered shading $35, delivered there by a mill which besides is unfavorably located in reference to that market. Here, there are rumors that contracts lower than $35 at mill have been accepted, and similar indications reach us from Philadelphia.

Old Rails.—We quote nominally $22@$22.50 for Ts.

Philadelphia. December 14.

Pig-Iron.—The only changes which have taken place in crude iron this week related to prices for some kinds of forge and foundry. A few days ago, several large transactions took place in inferior forge iron, and in consequence of this, some makers of brands which are called standard have been holding prices a little more firmly; but it is useless to try to advance prices at present; too many furnaces have heavy stocks on hand, and too many lots are offered on the market at buyers' terms. A few large consumers bought freely, but that demand seems to have been met, and at present there is no disposition to buy largely. Best grades of Foundry have sold this week at $21.50; some 25 to 50-ton lots sold at $20@$20.50. Numerous speculative inquiries are made, but the prices offered are too low to be accepted. Some authorities think that, on account of the smallness of stocks in second hands, an improving activity will take place in January, and they are willing to buy now, provided their offers are accepted. The strong companies are satisfied that nothing can prevent a strong movement, and are content with the present condition of things. Ordinary No. 2 Foundry sells at $19@$19.50. A little inferior is to be had at $18.50. Gray Forge, $18@$19 delivered. Nothing of desirable quality can be bought under $18.50. Two or three thousand tons have been offered on the market, and negotiations are pending, but prices asked are a little too high. In fact, if makers want to sell now for future delivery, they find it very difficult to move stocks above cost.

Foreign Irons.—Very little business has been reported this week. Some inquiries from Western parties are made; but it is doubtful whether more than $19.50 would be paid, and the nominal price is $20.50. A little Spiegeleisen has sold, and there are inquiries for large lots, but the best price to be had is under $29. Scotch Iron is selling very slowly, and buyers decline offers made from New York of lots of from 100 tons up.

Muck Bars.—From 600 to 700 tons of Muck Bars have sold from $32.75@$33.25.

Merchant Bar.—Considering the season, the demand for the past week may be called fair, but prices named are so low as to make it a matter of indifference whether mill-owners continue or not. Two or three mills will shut down this week; three or four country mills will certainly shut down; and it is said that others will follow next week. A very unsatisfactory trade is reported at country mills. The only good sales were of common iron, but prices are as low as 1·70c.

Sheet-Iron.—Local manufacturers of sheet-iron are reducing output, and are declining to make further concessions. Some large lots were refused, offers being too low, and nothing better can be done for buyers at present. The only demand is for thin sheets.

Nails.—Makers here report a rather slack movement, and jobbers backward as to next quarter's requirements. The action of the Western people has put a wet blanket upon this market. Nominal quotations, $2.80@$2.90; but buyers can make better terms. Offers are made at $2.60.

Plate and Tank Iron.—Several small sales were made this week at one tenth below usual quotations. Some manufacturers have inquiries in hand for next quarter's delivery, but can not secure business this month. There are offers for Plate at 2¼c. Shell sells in small lots at 2¾@3c. Flange, 3·80@4c. Fire Box, 5c.

Steel Rails.—There are rumors of inquiries for from 20,000 to 30,000 tons, but at present writing the orders have not been given out. Whether they will be placed before January is doubtful. Makers say that the restriction of output consequent upon the closing down of mills will prevent any further weakening tendency, and buyers who are offering $33 and $34 will be compelled to order at $35.

Wrought Pipes and Tubes.—A number of large orders have been placed within a day or two, and discounts are less.

Old Rails.—There are numerous inquiries from parties in the interior. Ordinary quotations, $22@$23.50 for Tees. Double-Heads, nominal at $25.

Pittsburg. December 12.

Rumors of the shutting down of mills, and the further restriction of the output of iron and steel, prevail throughout this section. Prices are weak and demand irregular. Standard brands of Forge are held at $17.50@$18. Sales of the Marshall iron have been made at about $16, and it is reported that some large lots will be quietly disposed of, and this has had an unsettling effect on prices. Cold-Blast Charcoal has sold at from $29@$32. Native ore coke iron, $18 for Foundry, and $17.50 for Forge. Muck Bar is offered at $32, with but little selling. Manufactured

Iron 1·70@1·80c. Business is unsatisfactory, and large consumers refuse to place orders until after January 1st. The rescinding of the resolution of the nail-makers to suspend production has checked business, and given prices a downward tendency. Quotations are $2.40@$2.50, with offers at $2.30@$2.35. Wrought Pipes are quoted at 7 per cent off, and Tubes at 60 per cent off. A sale of Old Rails is reported at $24.50. Several offers are in hand at $23.50@$24. Steel Rails sell in small lots at $36. There are offers at $35, shaded. Scrap is dull. There have been no sales of crop-ends. The Homestead Bessemer Steel-Works closed down last Saturday, and the Edgar Thomson Works will probably close this week. A good many mills are working half-time. A change in the situation of the glass trade is expected in a few days. The coke pool is not yet settled.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Dec. 14.

Anthracite.

Under the pressure of very unfavorable weather, the market continues exceedingly dull, and there is a general uneasiness among sellers as to the near future. It is well known that there is not cordial co-operation among the companies, and there are disquieting rumors which are not calculated to inspire confidence among buyers or sellers. So far as the former are concerned, the companies could not more successfully have destroyed confidence had they gone to work deliberately to do it. The mismanagement of the trade during the summer and early fall is now bringing its fruit, though it is only just to say that the state of the weather has aggravated the evil beyond the fears of those who have most disapproved of the hesitating and illogical policy pursued. There may be some comfort in the fact that the companies are even now beginning to discuss January, although, so far as we can learn, no decision has been reached concerning the action to be taken. If negotiations drag as they did in reference to December, work has been begun none too early. We trust that the present condition of affairs may prove a warning that will be heeded—a hope that will probably be regarded by many as strongly optimistic.

Buyers, encouraged by past concessions, are expecting all sorts of low figures, and it is difficult to move them from a position which unbiased observers are quite ready to admit is warranted by the facts.

Pittsburg.

Railroad trade is flat on its back for at least three good causes: Railroads themselves are not large consumers; for their engines are not as busily employed as a month ago. Then the rail trade, giving employment at this point to the largest class of mills, is dead, and shutting down is the order of the day. Pan-Handle pits are working less than one third time on an average. Some work quarter-time and some large railroad pits are shut down altogether. Among the latter are the Duquesne Works of the New York & Cleveland Gas-Coal Company, near this city, on the Pennsylvania Railroad. They employ over 200 miners. The Mansfield Coal and Coke Company, Pan-Handle region, closed two of its works, and smaller concerns are following suit. Quoit-pitching along the Pan-Handle is pursued to an extent that clearly shows how many idle miners there are at present. Prices are nominally 6¼@6½ cents on the wall, but actually are whatever the necessities of the seller make them. Sales at 5½c., and even less, are reported. Another reason for this dullness is the warm weather. No domestic consumer is in a hurry for coal, and the yard dealers are disgusted. Still another reason lies in the fact that this is the "off" season of the year in other respects. New contracts on account of lake and gas and other orders do not come in until early next year. The present is the hibernating season of the coal trade here, and this restfulness is only intensified by the extreme dullness of demand from iron and steel concerns and glass-houses. In fact, the trade has not been in its present shape for years, and I trust will not pass through another such period for years to come.

River operators join their growl with that of the railroad trade. With second pool coal selling at 7c. and less at Cincinnati and Louisville, the cloud over this trade here has not even a silver lining. Work is fairly brisk at the pits, for the reasons outlined in my last, but stocks below and the mild winter, added to causes already enumerated, conspire to make December, 1883, a dismal epoch in the history of the river trade in this city.

Buffalo.

One of the great improvements of the Lehigh Valley Railroad on the Tifft farm was completed Saturday, and operated for the first time. The work referred to is the mammoth double coal-stocking trestle, which is 2100 feet long, and the largest of its kind probably in the United States. Cars are to be run upon the trestles, and their contents dumped on to an elevated platform, under which is a tunnel 1385 feet long. There are 275 gates in the platform; and when these are operated, the coal is to be spouted into cars running through the tunnel. There is room for 96 coal-dumps in the tunnel, and it is estimated that one car can be loaded every five minutes. The platform has a capacity for holding 150,000 tons of coal at one time, and the company will thus be able to keep a large supply on hand to meet any emergency.

Three large Clyde-built steel propellers lately arrived here from Scotland—in sections—via the St. Lawrence River and canals, Lake Ontario, the Welland Canal, and Lake Erie. At Montreal, on their arrival from sea, it became necessary to cut the hulls in two, and the sections were placed on pontoons, thus enabling them to be taken through the shallow canals on the St. Lawrence route. These vessels are to run in connection with the Canada Pacific Railroad from Algoma Mills, Georgian Bay, to Port Arthur, Lake Superior, a distance of 350 miles, and will be fitted up for passengers as well as for freight. They can not leave here now, of course, until next spring, although the work of reconstruction is nearly completed. They will receive their upper cabins and other appointments at some place in Canada. The two other boats of the line will be sent from Scotland at the opening of navigation in 1884. The names of the vessels are the Algoma, Alberta, and Athabaska.

Horsford's Acid Phosphate.

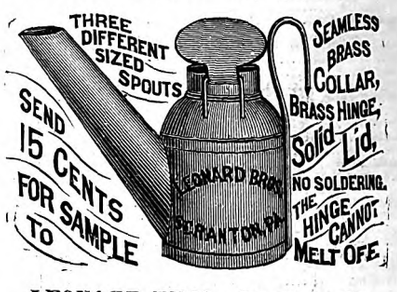
Admirable Results in Fevers.

DR. J. J. RYAN, St. Louis, Mo., says: "I invariably prescribe it in fevers; also in convalescence from wasting and debilitating diseases, with admirable results. I also find it a tonic to an enfeebled condition of the genital organs."

WANTED.—POSITION AS RESPONSIBLE business agent or manager of mines or metallurgical works, by a gentleman of long experience in similar positions in Nevada and Colorado. Address MANAGER, P.O. Box 203, N. Y. City.

OFFICE OF
VAPOR FUEL COMPANY,
Rooms 28 and 29 EQUITABLE BUILDING,
BOSTON, Mass., Oct. 3, 1883.

The VAPOR FUEL CO. is prepared to contract for the use of its process and to furnish the necessary Machinery and Apparatus.



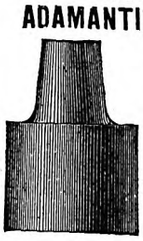
Iron and steel manufacturers, manufacturers using steam-boilers, smelters of ores, and others, are invited to examine the Process and inform themselves by seeing it at work upon a commercial scale. S. S. HENKLE, Pres.

TO INVESTORS.

The Keith Electric Company, having secured and paid for valuable patents covering a complete system of electric lighting, and having demonstrated the economy and reliability of their light, are now prepared to push its introduction with the utmost energy. For this purpose a limited amount of the stock is offered at $20 per share.

For full particulars address
AUSTIN GALLAGHER,
Drexel Building,
Corner Wall and Broad Streets, New York.

NEW MAKE OF MINE LAMP.



LEONARD BROS., Scranton, Pa.

ADAMANTINE SHOES AND DIES

WE MANUFACTURE THE ABOVE

ADAMANTINE SHOES AND DIES.

They have been in use on the hardest Quartz, both in the Territories and South America, for the past five years, and we warrant them to outwear three (3) sets of the best cast-iron. We also manufacture the best Rock Drill and Tool Steel in the market.

For further particulars, address
CHROME STEEL WORKS,
Brooklyn, E. D., N. Y., U. S. A.
S. H. KOHN, Proprietor.
C. P. HAUGHIAN, Superintendent.

When ordering, a rough sketch with full dimensions is all that is necessary.

MINING MACHINERY
INCLUDING
Steel Water Jacket Smelting Furnace,
Quartz Mills, Concentration Works, Hoisting Apparatus, and all classes of Machinery employed in Mining and Reduction of Ores.
PORTABLE AND STATIONARY
STEAM ENGINES
From Ten to Two Hundred Horse Power, Steam Boilers of any Style and Capacity.
SAW MILLS
Adapted to the wants of the Planter, Miner, or for the manufacture of Merchant Lumber. Prices ranging from
$200
Upwards, and of Capacity from 2,000 to 50,000 Feet per day. Shaftings, Hangers, Pulleys, Gearing, and all Appliances for the Transmission of Power.
LANE & BODLEY CO., Cincinnati,
Western Office: 50 Ring South St., Salt Lake City, Joseph M. Locke, C.E., M.E., etc., Consulting Engineer. *Treatise on Smelting and other Circulars sent Free.*
Sole Manufacturers of the Bruckner Revolving Furnace.

C. G. HUSSEY & CO.
COPPER AND BRASS
ROLLING-MILLS.
All sizes and shapes of Sheet and Bar Copper and Brass
ALSO
CRUCIBLES,
For Steel, Copper, Brass, Etc.
PITTSBURGH, PA.

DIVIDENDS.

HOMESTAKE MINING COMPANY, MILLS BUILDING, 15 BROAD STREET,
NEW YORK, Dec. 13, 1883.

DIVIDEND NO. 64.

The regular monthly dividend, TWENTY CENTS per share, has been declared for November, payable at the office of the transfer-agents, Lounsbery & Haggin, Mills Building, 15 Broad Street, on the 26th inst.

Transfer-books close on the 20th inst.

LOUNSBERY & HAGGIN, Transfer-Agents.

AUSTRIAN engineers are elated over the early completion of the Arlberg tunnel, in which the headings met on the 19th of last month. As compared with work at the Mont Cenis and St. Gothard tunnels, the Arlberg tunnel well illustrates the progress made in rock excavation through the introduction of power-drills and high explosives. Compared with the first-named enterprise, the advance of the heading was 2·6 times as rapid, and contrasted with the latter it was twice as fast. The original estimates of the engineers, as regards time of completion, were reduced in actual work by twenty-five per cent. The total length of the bottom heading is 10,259·4 meters, or 33,660 feet; in exactly three years, 9830 meters, or 32,251 feet, were driven, or an average of 9 meters, or 29·5 feet, per day.

A REPORT prepared by the Directors of the Richmond Consolidated Mining Company, for presentation at the meeting, shows that that company now holds upward of 10,000 tons of lead. Since the sale of 5000 tons in the summer of 1882, the company has not put any lead on the market. During the current summer, negotiations were repeatedly entered into, but the price then was not satisfactory. It has never fallen far below the figures which were then refused. Though not more than half of the stock is available here, it constitutes a standing menace to values which those in the trade should not lose sight of. One opportunity was missed this year, and it is not likely, therefore, that the chance of placing the metal as soon as there are signs of improvement will be allowed to go by.

THURSDAY last was one of the red-letter days in the history of American engineering, the occasion being the formal opening of the great cantilever bridge spanning the Niagara. Though as yet the official report of the experts—Messrs. GEORGE S. MORRISON, CHARLES MACDONALD, THEODORE COOPER, CHARLES LILIENTHAL, and THOMAS RIDEOUT—has not been made, it is understood that the tests made by them have been of the most satisfactory nature. Ten locomotives and eleven loaded gravel cars on each of the tracks started over the bridge stopping on each arm of the cantilevers and on the center truss. The maximum deflection when the trains reached the middle of the bridge was 6·75 inches. Apart from the principles of which the bridge is practically the first embodiment, the remarkable feature connected with it is the rapidity of its erection. Work was begun on the 19th of April, and in less than seven months and a half it was completed, the work being finished on the first of this month. The credit to be awarded is due mainly to the genius of C. C. SCHNEIDER, the engineer.

THE protracted sharp competition in the Connellsville coke trade, with its attendant evil of very low prices, has at last brought about the partial realization of a plan designed to remedy existing evils. For months, coke has been selling f. o. b. cars at oven at from 90 cents to $1 per ton. When it is considered that it takes fully 15 tons of coal to make a ton of coke, and that the cost of coking must be taken into account, it will be understood that the coal brought to surface is paid for at a rate less than 50 cents per ton. Such figures are well calculated to make the weaker producers uncomfortable, and there is some reason to believe that the strain put on them by hard times is purposely made greater. There has been a gradual but, it would appear, almost irresistible tendency in the Connellsville region toward centralization of interests, which low prices like those ruling are very apt to assist. But even at bed-rock prices, there has been a constantly shrinking demand, a state of affairs due principally to the stagnation in the iron trade. As a last alternative, the coke-makers have decided to restrict, stopping one day in the week, and making 72-hour instead of 48-hour coke. This amounts to a reduction of the output of 3600 cars per week, or approximately 15 per cent. More than two thirds of the 8400 ovens now in blast are included in this agreement.

THE labor question is one that may cause some agitation during the ensuing year, notably in Colorado. During the past few months, there have been local contests which may possibly be regarded as the forerunners of a more general discussion of the relations of employés to employers. The most intelligent of the latter shrink from the idea of any readjustment of wages, and many reject the possibility of seeking a reduction of cost of production in that quarter. It has been urged that the conditions in the West are wholly unlike those in the more thickly settled parts of the East, where there are many diversified industries and where there is a steady demand for labor in agricultural pursuits. In Western mining camps, it is pleaded, there is nothing but mining; the cost of the bare necessities of life are high, and there is no margin whatever for any reduction. The labor is such that it demands the highest physical development, the miners must be a picked body of men in that respect, and can and do claim wages higher than those of ordinary labor. There is, of course, much that is forcible in such an argument; but it does not weaken the power of hard facts. When any enterprise has reached the point where it becomes a question whether, in the interest of those who have embarked in it, it is better to suspend or to ask the employés to bear their share of the common burden, we believe that common sense will dictate the taking of the latter alternative. Under the circumstances, knowing the temper of their men, the majority of the mine owners of the West will be forced, however, to bring their miners to a realizing sense of the gravity of the situation by closing down, whenever they can do so.

The Morey & Sperry Pulverizer at the Welcome Mine, Deadwood, Dakota.

EDITOR ENGINEERING AND MINING JOURNAL :

SIR: The Deadwood *Times* of December 12th contained an article headed "The Welcome Mine," part of which was so utterly devoid of truth that we would thank you if you would allow us to make a correction of the same through your paper.

The Morey & Sperry Mining Machinery Company did make and furnish the Welcome Mining Company with splendid engines, boilers, and first-class machinery, including two 5-foot size Morey improved pulverizers, and a complete gold and concentrating plant.

When ready, all was started up, every thing working splendidly, as stated in the *Times;* but they then state, further, that in a short time they had broken the pulverizers all to pieces, and proved them to be worthless, which is utterly false.

We have seen a letter over the signature of the president of the Welcome Company, referring only to the breakage of a cage or carrier, and the second die, or wearing part, and stating that then the mill shut down, and the men were discharged; that the gold was showing well on the plates; and that concentrates assayed $100 per ton, or words to that effect.

There is not a stamp-mill in Deadwood that has not broken shoes and dies and cams lying around its mills. They do not, however, when their mine is paying, shut down their mills because a couple of wearing parts are broken: they put in others, and push the crushing.

We shipped with that plant several extra wearing parts. Why did not the Welcome Company put in others "that it had on hand," and continue to work if its mine was paying and if it had plenty of water; then order more wearing parts of steel, which can not be broken; as we offered it steel parts at twice the price of cast-iron, and it ordered the iron. No one can guarantee that cast-iron will not break.

Mine managers do not usually shut down their mine if they can make from $300 to $400 per day, if it does cost them a few dollars a day for wearing parts.

We have the further statement of the company's master-mechanic, who erected its mill, and to whom the Atlantic Steam-Engine Company gives a good name and reputation, as he was its foreman a number of years.

This gentleman states that he ran the mill about a week after erection to get it into running order, and that the pulverizers each crushed over thirty tons per day. Yours very respectfully,

JAMES D. SIPP,
Sec'y Morey & Sperry Mill Co.

THE MINES OF FRESNILLO.—I.*

Special Correspondence of the Engineering and Mining Journal.

An important memoir on the silver mines of Fresnillo has been recently prepared by Professor Silliman, for the owners, and printed for private circulation. It embodies a history of these famous mines; it reprints the references made to them by Duport, Burkart, and others, and contains summaries of the accounts taken from the official records of the companies which have worked them since 1841. This latter section is of peculiar value to the metallurgist, as it gives precisely the cost of treatment and the percentage of loss by the patio process at the Hacienda Nueva of Fresnillo; and it shows authoritatively what has been the actual yield of the ore of one of the large productive mines of Mexico. The document was evidently prepared for the purpose of affording capitalists the means of forming an opinion as to the advisability of reopening the deep workings. This being the motive for its publication, we are struck by the palpable honesty with which facts are stated and arguments and apologies withheld. If all mining enterprises seeking for public support at home or abroad were presented with the same candor, mining would soon be relegated from the domain of speculation to that of business reality.

We gather from the memoir that the Fresnillo mine is on a net-work or *Stockwerk* of silver-bearing veins which intersect the Cerro de Proaño, a hill with a circumference of only 3000 meters, and rising isolated from the plain to a hight of 350 feet. On this low hill, some twenty-one shafts are sunk, varying in depth from 30 to 420 meters, through which, in the palmy days of the mine, 900 tons of selected ore were raised weekly.

The mines were, according to tradition, discovered and superficially worked soon after the Spanish conquest—a fact likely enough, as it is certain that most of the large mines of Mexico, from south to north were known to the conquerors, and robbed by them of their most accessible mineral. It was either by dint of that keen instinctive scent for gold and silver which the Spaniard has always exhibited, sharpened by the cupidity which was the ruling motive of the followers of Cortez, or, more probably, owing to the mines having been already worked for native and easily reducible ores of silver by the Indians before the conquest; but certain it is that, within a generation, that little band of Spaniards had ferreted out all the great deposits of precious metals more effectually than our large army of prospectors has unearthed those of the Rocky Mountains within the same period of time. But the active exploitation of the Cerro de Proaño dates from 1750, when, for a few years, its principal veins were worked down to water-level. How to cope with the water was then, as it is to-day, the puzzling problem and the hinge on which profit or loss turns.

After the revolution in 1830, the mines were appropriated and worked by the State of Zacatecas, which in 1832 made them over, in return for a division of profits, to the Zacatecas-Mexican Company. As depth was attained, the water increased. The *malecates*, or horse-whims, though worked by 1500 horses, could not master it. In 1836, a 60-inch cylinder Cornish pumping-engine supplanted 35 horse-whims. Shortly after, another of equal power was added. But their combined capacity was insufficient in 1842 to unwater the lower workings, and they were replaced in 1844 by two new 80-inch cylinder engines, the old engines being removed to the reduction-works. The new engines permitted work to be prosecuted (in the Balena mine) to a depth of 400 meters. Matters prospered for many years thereafter under the management of Don José Gonzales Echeverria; but progress was interrupted by the political troubles of 1857–67. The accounts show a decline in yield. Echeverria was exiled. Politics occupied the attention of the rich, and the poor were drafted into the army, to fight their masters' battles. Meanwhile, the water obeyed its laws implicitly and filled the mines. Since then, the deeper workings have been flooded to a depth of 1072 feet; and as it is estimated that the cost of pumping will be $1000 per yard, the item of unwatering alone will amount to about $400,000. However rich, therefore, may have been the mineral in the bottom of the Balena and San Francisco shafts, it is easy to understand that no native organization would undertake to corroborate the old reports; and, reckless as is foreign capital, even during periods of speculative mania, it would hardly risk so large a sum on such a venture. But as much more shallow workings of reputed value were submerged, it would not be necessary to stake the whole amount in determining the character or the condition of the deepest workings. It may happen, and is not unlikely, considering the methods of Mexican timbering, as the workings are on an intricate net-work of veins in a decomposable porphyritic gangue, and have been under water since 1860, that they have caved in, and that therefore it may be cheaper to reach the ore in depth by a new shaft than to unwater the old one. The hopeful feature of the enterprise is, that as much as 300 tons weekly are still extracted from the hill, chiefly through the Amarilla shaft, from the fifth level, and that into the harder ground beyond the Cerro de Proaño the veins are known to extend and to be productive, but have not been exploited, owing to the greater cost of mining and crushing. The advent of the railroad with cheaper fuel and supplies will undoubtedly reduce these items of expense. Oxidized ores were found to a depth of about 200 feet; but they are now scarce. Beneath this decomposed layer, the ore carries sulphureted compounds of silver, with some native silver and more or less of the sulphides of the common metals. A peculiarity, however, which this region possesses with some others, as pointed out by Professor Silliman, and one which compensates for the extreme narrowness of many of the veins, is, that for from half a foot to 2½ feet from the veins the country-rock is enriched by impregnation with silver minerals to a grade equal to that of the vein-matter itself.

In the early days of the resuscitated work, 1830–33, Auld and Buchan put the value of the ore of all kinds at 8 marks 7½ ounces per ton—about 60 ounces. But the tabulated return given on page 66, from 1853 to 1862, shows that there were treated during that period 452,264 tons, and that the silver produced was 1,096,281 marks, or 2·42 marks per ton, equal to 17¼ ounces. During the same period, the cost of mining, including pumping, was $1.632 per carga of 300 pounds = $10.88 per ton, while the cost of metallurgical treatment was $11,169, giving a total of $22.04 per ton. The value of the silver produced was $9,825,595.68, or $21.72 per ton treated. This exhibits, therefore, a slight loss on working expenses; a loss accounted for by M. Ramosa, but still honestly published. The cost of mining and treatment shows, from year to year, considerable variation. The rise or fall in the column of mining, generally corresponding to a similar oscillation in the column of treatment, is probably due to the region of the mine whence the year's supply was drawn, the oxidized surface ore costing less for extraction as well as for reduction than the deeper more rebellious ores. The annual yield per ton also departs often from the average. Thus, while the average of the ten years shows a loss of $0.32 per ton, the result for 1856 shows the cost per ton has been $21.45, and the yield per ton, $23.44, or a gain of $1.99 per ton.

From Duport's notice of Fresnillo, reproduced in full in this memoir, we find that, from January, 1840, to October, 1842, the yield of silver was $49.18 per ton; but he incidentally remarks that, owing to better administration and reduced cost in all departments, ores too poor to be handled in times past were then beneficiated; and it may be that, in a still later period, the attempt to work up quantity may have been carried beyond the limits of economy; but nevertheless, the figures furnished leave no doubt that Fresnillo is not exempt from the law of depreciation in depth which seems to prevail so universally; for, according to Auld and Buchan, the yield in 1833 was 8 marks 7¼ ounces, say $60. According to Duport, it was, in 1840–42, $49.18. According to official account for 1853–62, $21.72. A sliding-scale unfortunately downward, which it would behoove all contemplating the reopening of deep mines to ponder over.

It is interesting to note the great reduction in cost through the introduction of steam. Even in 1832, when the mines were comparatively shallow, the lowest depth being but 40 fathoms, according to Auld and Buchan, the cost of unwatering amounted to $300,300 per annum, 300 men and 1500 animals being constantly employed at the *malecates*. They add, in advocating the application of steam, certain facts ascertained by comparing the work of horses on the Veta Grande with that of the steam at Bolaños, namely, that by the combustion of 832 pounds of wood, the same quantity of water was raised as by the labor of 48 horses for twenty-four hours at the *malecates*, or that the effect equal to that of a whole day's work of a horse at the *malecates* was obtained by the consumption of 17 pounds of wood; that is, by a less weight of fuel than the weight of the forage which the animal would eat in the same time. In those early days, in addition to the animals at the whims, 200 were employed in hauling ore and 500 in the reduction-works, or 2200 in all.

According to Duport, who wrote in 1842, when the building of larger engines was in contemplation, and the deeper workings were 800 feet from the surface, the cost of unwatering was $2934 a week, as against $5775 a week for unwatering in 1833, to a depth of 240 feet. In 1844, the cost of pumping with No. 2 engine had risen to $3250 a week. But from 1853 to 1862, when the two larger engines were in operation, the total cost of unwatering was only $1,100,301 per annum, or $2116 per week.

The price at which the railroad will be able to deliver coal on the Central Plateau is uncertain. If a brisk export trade should spring up

* *Sketch of the Great Historic Mines of the Cerro de Proaño, at Fresnillo, State of Zacatecas, Mexico.* 1883.

Digitized by Google

between Tampico and England, coal should be delivered at that port for from $5 to $6. Tampico will be about 400 miles from Fresnillo. At two cents a ton per mile, the freight would be $8, and the total cost from $13 to $14. As wood now costs $7.50 per ton, there will not be much advantage in using English coal. But the coal-fields of Sonora will sooner or later be brought within reach of the great mines of Zacatecas, Durango, Guadalajara, and Guanajuato, and probably other and nearer sources of fuel discovered. Then, with cheaper fuel and cheaper supplies, it will not be necessary to alter present methods in order to render remunerative many a mine now bankrupt; for this important memoir, with its exact data, adds ample testimony to existing proof of the efficiency and economy of the patio process, when worked skillfully under proper conditions of climate and ore. NEW PUBLICATIONS.

SECOND GEOLOGICAL SURVEY OF PENNSYLVANIA. Vol. I 4. *Geological Report on Warren County and the Neighboring Oil Regions, with Additional Oil-Well Records.* By JOHN F. CARLL. With a Colored Geological Map of Warren County; Two Sheets of Oil-Well Sections; and a Map of the Warren County Oil Region. Harrisburg. 1883. Octavo, 439 pages. Price, including postage, $1.37.

The great interest and value of Mr. Carll's reports on the oil regions have long been acknowledged. His work has combined in a striking manner the patient accumulation of facts and the deduction of laws useful to practical operators, with the development of theories in geological history most suggestive and instructive to scientific geologists. The latter class is likely to receive the greater benefit; but that is not the fault of Mr. Carll. He has been, in fact, more earnest and active in the compilation of records, and the utterance of advice and warning to oil operators, than in his brilliant demonstration of the dynamics of the ice period and the reversal of the drainage of the country. But it almost seems as if the attitude of the "practical operators" were less favorable to his work now than when he began. The gambling spirit (which hates the precise truth, since it lives by uncertainties) was always rife in the petroleum business; but gambling in petroleum appears to have reached a hight, in the last two years, which it never before attained. One of its results is the desire on the part of those who bore wells not to furnish, but to hide or to misrepresent, the facts of their experience. Another result is the habit, bred by gambling, of looking at immediate consequences, short turns, artificial changes—any thing, in short, rather than the true condition of the oil business considered as a drain upon natural resources which can never be renewed. We have already commented upon the strange spectacle presented by this industry—reckless overproduction; ruinously low prices; hundreds of eager adventurers running a mad race of waste, as though it were a virtue to be first in throwing away for almost nothing the wealth that nothing would bring back. The approaching exhaustion of the oil-fields causes nobody to pause. "The trade" hoots at the warnings of the calm outside observer, who draws from the facts their inevitable conclusion; and, lest more facts should strengthen the force of the demonstration, the gamblers *hide* them at the time when they would be most valuable for public guidance. The facts are but cards in their little game; and they are not fools enough to show their hands! Well says Professor Lesley, in the introduction to the volume before us, "The next generation will gather from our oil history, with angry astonishment, a lesson of warning in political economy, only useless because it comes too late."

If any spectacle could illustrate the fallacy of the *laissez faire* policy in industrial matters, it would be, one would think, this amazing waste of wealth, without the raising of a finger of interference on the part of the government. If Pennsylvania were infected with the theories of free trade, one might understand this phenomenon. It could be plausibly explained as a consequence of the belief that every industry should be let alone. But that is not the heresy of Pennsylvania.

When Mr. Carll gave to the world his reasons for apprehending relatively early exhaustion of the oil regions—every one of which reasons remains in force to day—there were many sneers at scientific theorists; and when, not long after, some immensely productive wells were opened in Cherry Grove, there was a general outcry of triumph, as though this discovery had overthrown all Mr. Carll's conclusions. But the new bonanza was speedily exhausted. The Jamestown well began at the rate of 200 barrels on May 17th, 1882; by the 28d, it had reached a daily yield of more than 1000 barrels; and its maximum of 2000 barrels was attained about the middle of June. By the latter part of August, the product of the district was probably 40,000 barrels daily. In September, it began to decline rapidly; in December, it was between 2500 and 3000 barrels a day; of the 405 wells which had been bored, 22 had always been dry, and of the 383 productive ones, fully two thirds had ceased to yield oil; and the product of the original Jamestown or "Mystery" well had sunk to less than one barrel per day. Professor Lesley says:

"The recent discovery of an abundance of oil stored away in a small area south of Warren, which produced so disastrous an excitement, and added such a pile of fuel to the gambling fire of the oil exchanges, seemed at first to overthrow the scientific conclusions of the survey. But the small extent and rapid exhaustion of this pool of oil have shown the soundness of our acquired knowledge; for it is merely a repetition of what has happened before and what may happen again. It is not from such local pools that the vast demands of trade are to be supplied. Spurting and flowing wells are no longer marvels of nature calculated to upset the principles of geology, and therefore to let loose the demon of unreflecting speculation upon the community. The figures given in this report will satisfy reasonable people that such events are mere ripples in the stream of oil production, and, if they affect the market, are made to do so by shrewd and heartless monopolists for their own purposes. It is equally manifest that violent fluctuations of the market would be impossible but for a still prevalent ignorance of the geology of petroleum, and an equally prevalent epidemic of the gambling spirit."

The account given by Mr. Carll, on page 366, of the proceedings connected with the "Mystery" well, affords a graphic illustration of this spirit. The drillers, oath-bound to secrecy; the picket-lines and patrols guarding the premises night and day; the plugging of the well after oil had been found in it; on the other hand, the scouts who filled the neighborhood, "scanning the derrick and tools with field-glasses, examining the stream below for indications of oil, listening to hear if any flows occurred, and hoping for an opportunity to steal in unobserved or to bribe some one of the guards"—these are dramatic elements. After Pennsylvania shall have fooled away her oil, such scenes will at least be material for the novelist as well as the moralist.

Mr. Carll's report is accompanied with maps, and a statistical chart of great interest, showing the annual product of oil, by districts, in Pennsylvania and New York, the average price per barrel of crude oil at the well for each year, and other data, from 1859 to the close of 1882. Not only the decrease in price from $9.87½ in 1864 or (not to regard these war prices) $3.64 in 1872 to $0.78¾ in 1882, but also the rise and fall of each district, may here be read at a glance. It is pathetic to note on the chart the appearance, increase, and diminution of one color after another, symbolizing the rapid development and premature exhaustion of a new territory. Oil Creek, Pithole, Tidioute, Butler and Armstrong, Clarion, have waxed and waned. Even the marvelous product of Bradford, 22,300,000 barrels in 1880, and 23,000,000 barrels in 1881, had fallen in 1882 to 18,000,000 barrels; and the grand total of 1882 was swelled to 30,460,000 barrels, as against 27,238,000 in 1881, only by the short-lived spurt of Cherry Grove (increasing the yield of Warren and Forest from 440,000 to 3,300,000 barrels), and the large contribution of Allegany, New York, which rose from 600,000 to 6,450,000 barrels in the latter year. Meanwhile, the ever-increasing stock on hand—amounting at the end of 1880 to 18,928,430; a year later to 26,019,704; and at the end of last year to 34,596,612—gives solemn proof of the uselessness of this reckless production. This chart, pasted on the wall, should be intelligible to President Belshazzar of the Standard Oil Company, even without the aid of a second Daniel come to judgment for its interpretation.

DANGER FROM SIGILLARIA IN COAL-SEAMS.

In an interesting paper read before the Manchester Geological Society by Mr. George Wild, it was stated that there was much doubt in the minds of many persons whether the casts of the trunks found in the roofs of many of our coal mines, and known to the miners as "pot-holes," were really organic casts of plants, or were due to gases escaping from the decomposing and probably liquid mass of matter forming the coal, in the form of bubbles, which, bursting, would let in the soft covering of muddy sediment or roof, forming a cast surrounded by a film of carbonaceous matter. That hypothesis might be very sparingly allowed to account for some of the irregular casts that were sometimes met with; but there was no doubt that other causes were in operation, playing an important part in determining the shape of the bastard "pot-holes." He did not, however, intend to advance any definite opinion as to short crumpled-topped holes from which the cast had dropped, but he would briefly allude to the more perfect ones. It had been his duty for a long time, as it was of all colliery managers, on scientific grounds.

That the growth or presence of roots and rootlets in the seat of a seam of coal had unstratified the shale, most old sinkers will admit, especially in strong ground, where planes of stratification or floor-partings were eagerly sought for to assist in making way for the measuring tapes. He thought no colliery manager could with advantage ignore geological phenomena indicative of a danger the creation of which was in no way due to either unskillful planning or negligence on the part of any one connected with colliery operations. By the observation of these phenomena, accidents were more likely to be avoided in the many contingencies that had to be guarded against underground. It behoved them, therefore, to take advantage of every means that presented itself for detecting so treacherous a foe as the hidden "pot-hole," or the silently yet suddenly falling slickensides in the roof of a coal mine. The basis of these stool-bearing trunks could be recognized, not only by the roots themselves, but the crucial and quaternary divisions which were seen directly under the base of the pot-hole, where the stigmarian punctures were almost obliterated. Had it been only possible to detect these objects by the features simply of the upper surface, then no economic value would attach to a knowledge of their form further than they already possessed—that their separation from the surrounding strata by a film of coal, and their upward taper, rendered them dangerous to work under.

The conclusion that these short portions of trunk had in most cases been hollow to the level of the seam of coal with which they had become incorporated, was borne out by the fact that often the deposit of fishes' scales, teeth, spines, etc., and bituminous shale on the top of the seam, had been continuous almost evenly with the roof through the hollowed trunk—a circumstance easily accounted for when under the same depth of water as the surface of the seam, and sufficiently decomposed to have become hollow. Many objects of interest were to be met with in the roof, as well as its being that part of the underground workings requiring the most attention from both workmen and officials, and assuredly it would not be beyond the duty of the highest official to examine the various features which presented themselves. The aim of the paper was not only a small contribution to science, but also to the mining interest generally, in the avoidance, however slight, of one or more of the greatest sources of danger attaching to coal mining, a matter of no little importance to both employers and employed.

A NEW SAFETY-CAGE.—The tests with a new safety-cage, recently made at Falkenau's iron-works, Leadville, Colo., were witnessed by a large number of mining men. The results were entirely satisfactory to every one present. Mr. Falkenau has also devised a safety-hook, which will automatically detach the cage from the cable if drawn up into the sheave. The device was pronounced excellent.

THE Pittsburg & West Virginia Railroad has purchased one of Hasenzahl's diamond-bit rock-drills for prospecting purposes. Mr. Hasenzahl has also recently furnished the McNabb Coal and Coke Company, of Chattanooga, Tenn., with a special size of his drill. The machine is adapted to boring two sizes of holes, 1¼-inch and 3¼-inch, and is furnished with two diamond bits and boring tools, hose, force-pump, and tool-rods all complete, for going to a depth of 500 feet. The McNabb Coal and Coke Company will use it in prospecting on its lands on Walden Ridge, Tenn.

SKETCH OF THE METALLIFEROUS DEPOSITS OF FLINTSHIRE AND DENBIGHSHIRE, WALES.*

The counties of Flint and Denbigh form the northeastern portion of the principality of Wales. They are largely productive of lead and zinc, in the mining and smelting of which a considerable proportion of the working population is employed. Mr. Davies, a well-known writer on metalliferous deposits, has added a contribution to our literature of the subject, which is of particular interest to American miners, who, during the past few years, have had so much to do with deposits in limestone formation.

The oldest known strata of the two counties are the lower Llandeilo or Arenig beds, followed by a succession of strata which, by our school of geologists, is looked upon as the Llandeilo series proper. They are capped by a dark fossiliferous limestone. This series of strata forms the great mineral horizon of the Silurian strata of Wales and the borders. It is in these strata that the lead mines of Carnarvon, Merioneth, Montgomery, Cardigan, Carmarthen, Pembroke, and Shropshire are worked, though in Denbighshire no lead mines have as yet been successfully developed in the group. Then follows a series of strata known in North Wales as the "Bala," and in Shropshire as the "Caradoc" group. Above, come the Llandovery beds, very fossiliferous strata, which are capped by a series of pale shales and slabs known as the Tarannon shales. These are followed by the Wenlock shales, forming the lowest, and the Denbighshire grits, forming the upper portion of a series of rocks of vast thickness in the aggregate. Above the latter, comes a deposit which in Denbighshire seems to represent some portion of the Devonian strata, and then the most important member of the stratigraphical series is reached. It is the "Mountain" or Carboniferous limestone of North Wales. This limestone is covered by a series of sandstones, chert, and pebble beds, thin limestones and shales, which collectively are taken to represent the millstone grit capped by the Coal Measures.

The lowest division of the Carboniferous limestone is a series of white-colored limestones, ranging in thickness from 70 to 130 yards. They contain metallic ores to the extent and in the manner to be described. The second division consists of a thick series of pale cream, pink, and gray-colored limestones, from 100 to 170 yards thick, which form the most usually productive ore-bearing group of any of the limestones. As a rule, these two lower divisions thicken in their progress northward. The third division is exceedingly rich in the remains of former sea life, but, save for the "flats" that are formed on their uppermost surfaces, they are barren of metallic ores. Above the dark fossiliferous limestones and shales, a series of calcareous sandstones in the lower part lead up through a succession of red, yellow, and white sandstone beds to massive white grits over twenty-five yards thick. The latter, in their turn, are overlain by a limestone bed, seven yards thick, and cherty rocks capped by shales and sandstone. Both the limestones and the overlying sandstones are traversed along their whole course by numerous fissures or cracks. No less than 170 are laid down on the maps of the Geological Survey, though this number does not probably nearly represent the entire quantity. About 160 of those already observed have a general east and west direction, ranging, however, from N. E. to S. W., and from N. to S. E.

These fissures are of two principal kinds. First, there are simple cracks of greater or less width, which seem to have been formed by the contraction of the rocks as they dried and hardened. The greater part of the fissures ranging on either side of E. and W. are of this description. Secondly, there are fissures that follow lines of displacement of the strata. These have two principal directions: first, north and south; and secondly, east and west, or rather from northwest to southeast. Those running north and south are known as the great "cross-courses;" and the strata are generally thrown up by these to the east, although there are a few exceptions to this rule. In the east and west lines of displacement, the upthrow is usually to the south.

The north and south fissures travel long distances. One extends from near the great east and west Minera fault, south of Llanarmon in Yale, to the sea, a distance of fifteen miles, and is known among the miners as the "hell-gallop" cross-course. As this fissure passes along Halkyn Mountain, it has a width of from ten to fifteen feet.

There are one or two other roughly parallel faults, but these do not extend to so great a distance. The east and west fissures of the first class traverse short distances; but those on lines of displacement—as the great Minera fault—may be followed for many miles.

In point of age, the simple cracks or fissures seem to be the oldest, because they do not often pass upward through the shale. The north and south cross-courses come next. They pass up to the surface. Then come the great east and west lines of displacement, which appear to be the latest in time, inasmuch as, taking all the faults of the region into consideration, they displace whole groups of north and south faults.

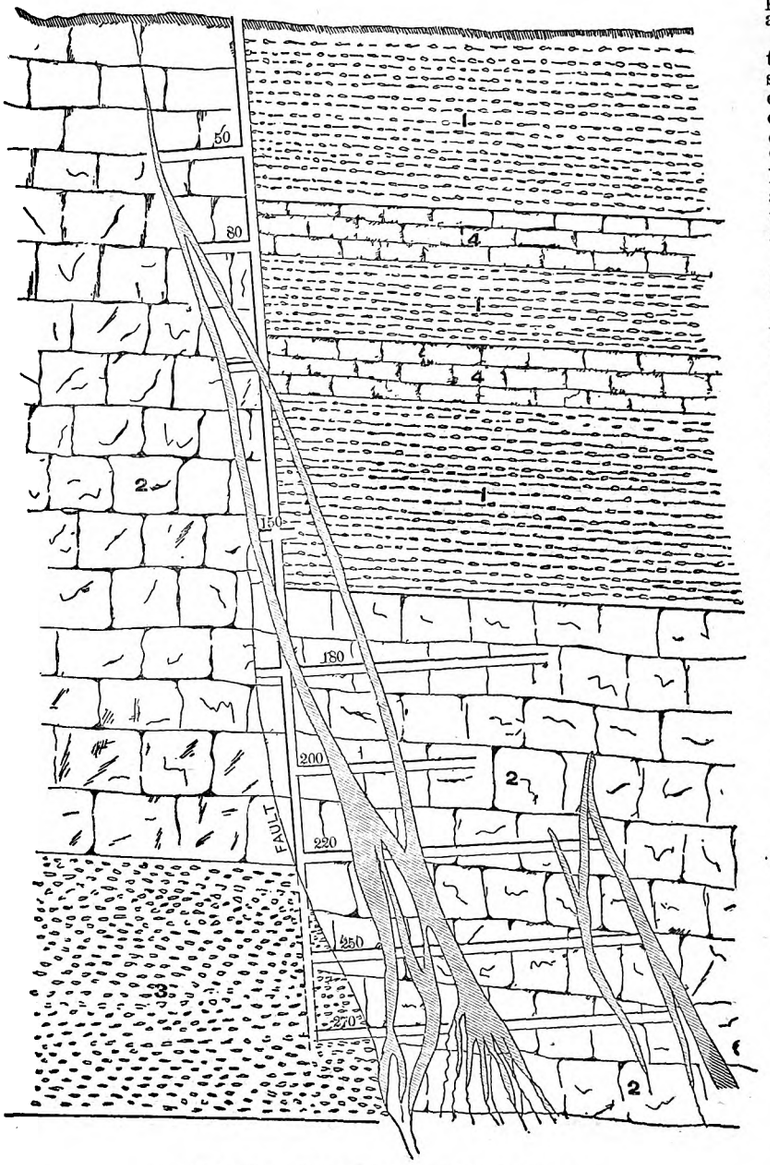

FIG. 8.—MINERA LEAD MINE.

1. Millstone Grit. 2. Carboniferous Limestone. 3. Shale Beds. 4 Limestone in Millstone Grit.

From the fact, probably, that these cracks and fissures in strata generally have "led" explorers in past times to hidden deposits of wealth, has come the name "lead" or "lode," by which they are known in mining language, and by which they may now through the remainder of this article be named.

The east and west lodes, comprising the whole group having this general direction, vary in width from six inches to as many feet. They are, as a rule, narrowest as they pass through the lowest compact limestones, and as they traverse similar beds in the overlying group. They open out where a bed of softer rock or a succession of thin beds comes in, especially where the calcareous matter is partly absent, and the rock is made up of sandy material. They are wide, but disordered as they pass through shaly or clayey beds. They open out into "flats," as we shall see, at the junction of sandstone with limestone beds. They are disordered, or lost downward, when the underlying old red sandstones and shales, or the Silurian strata, are reached; and for the most part, they are lost upward when they reach the shale. They generally dip or hade toward the north, but their inclination varies as they pass through different strata, and they are sometimes deflected from a straight course as they pass through beds of shale and marl.

Branching out from the main lodes are "fliers," or subsidiary cracks. These sometimes die out and are lost as they are followed into the adjoining strata. Sometimes they meet with other cracks that start from a distant part of the lode, and sometimes, making a little bend, run roughly parallel to the main lode, and in a short distance rejoin it.

The cracks that diverge at the greatest angle from a main lode are probably of the same age as the latter, while those that are more or less parallel to or curve round to meet the main lode are of a later date. More especially is this the case with those that occur on the upper or "hanging" side of a lode. These latter are due, probably, to the falling away of the strata by its own weight from the superincumbent rock into part of the space formed by the main fissure.

Besides these true fissures or lodes, there are other two varieties of depositories of metallic ores which we have to consider. These are, first, "flats;" and secondly, "pockets," "vuggs," or "ore-chambers."

The "flats" are of two principal kinds. The first class consists of those that occur at the junction of two dissimilar beds of rock. There are two distinct horizons at which "flats" of this kind occur. The lowest is found at the base of the grits, lying upon the dark uppermost beds of the main limestone *E*, and the uppermost in the chert, overlying the limestone band of Fig. 1.

In both cases, between the limestone and the overlying sandstone, there is a thin parting of shale or clay, which is softer than either the limestone or the sandstone. On both sides of the more or less vertical fissures or lodes, and to a distance varying from two or three to thirty and even forty yards, the sandstone has been decomposed to a hight of two or three feet. This decomposition may have taken place in the following manner:

The cracks are more restricted in passing through the limestone than they are as they traverse the sandstone. Therefore, a column of water passing through the overlying sandstone would be partially arrested when it reached the limestone; and, assisted by pressure from above, would gradually soak along the line of soft parting, softening it and the the overlying sandstone immediately adjacent; and in process of time, either washing it away or reducing it to the consistency of mud, would prepare it to receive the deposition of any heavy substances the water might bring with it.

Flats of this description resemble most nearly those occurring in the carboniferous limestone of the North of England, with this difference—there, it is the limestones themselves that are eaten away, while in Flint

Digitized by Google

and Denbigh the limestones are intact, and the overlying sandstone has been removed. Thus, the three "flats" that are found in the great limestone of the North occur in beds of limestone that are parted by thin layers of shale. This difference is accounted for by the fact that in the North the limestone is overlain by "sill," or hard shale, but in Wales by sandstone, more easily acted upon by water.

The "flats" of both districts have, however, this fact in common—they occur only in connection with fissures or lodes traversing the strata in which they occur, and they are not found except in this connection.

The second kind of "flat" occurring in the district we are considering partakes more properly of the character of a flat crack or lode. An example of this kind is seen in the North Hendre flat, Fig. 2. It would seem as if the beds below had either shrunk by contraction, or sunk through the giving way of some lower bed, thus causing a crack like that we often see in a wall built on a poor foundation. The crack has been enlarged in the course of time, and subsequently filled with its present contents. It will be seen that this flat occurs at a much lower horizon than those we have just noticed.

A third form of "flat" is conceivable where a crack coming down on a shale-bed runs some distance down it, and then strikes downward at some weak point of resistance. In such a case, the shale-bed is gradually removed, and the space subsequently filled with metallic and other minerals.

We now come to notice the class of ore-deposits known as pockets, vuggs, cavities, or ore-chambers.

Any reader who is familiar with the limestone beds we are considering, as they are worked in quarries along the course of the belt, will have noticed that there are, in the middle and lower divisions, irregularly shaped masses of rock of a different character and composition from the rest of the beds. They are marked by a comparative absence of lime and a preponderance of sand in their composition. They occur in all stages of decomposition, and are mostly of a brownish color, from the presence of iron. In places, this loose sandstone is full of small cavities. Again, it is partly washed away, especially where cracks come down upon it and lead away from it. The result is caverns in the incipient stages of their formation.

Where water has had free ingress and egress to these deposits, the result is a cavern. Where, at some period, the egress has been closed, or partly so, the result is a pocket more or less filled with clay, carbonate of lime, and brecciated or conglomeritic fragments of limestone, in which metallic ores may also be found.

Such cavities also occur along the north and south lines of fracture, where the rock on both sides of the main crack is shattered. A succession of these is seen along the cross-course west of the Park mines, Minera, and from Halkyn to Holywell.

It will be borne in mind, however, that, in order to transform a cavity into a pocket which may contain metallic ore, the outflow of water must, if not altogether stopped, be checked and rendered very slow.

Locally, the name of "flat" is also given to these pockets when they contain lead ores, as in the case of the extensive one at the Prince Patrick mine, Halkyn.

The whole of the fissures, cracks, flats, and most of the cavities, just described, have during the course of time become filled with substances which may be broadly classed into two kinds—earthy and metallic.

Strictly, speaking scientifically, some of the earthy materials have a metallic base, and are known in mineralogy as belonging to the metallic elements; but the word earthy is used here in a practical sense, to distinguish the ordinary matrices of the metallic ores from these ores themselves.

The earthy filling of the fissures and cavities is almost made up of the materials forming the strata the fissures pass through, or in which the cavities occur. They appear in two principal forms. First, as fragments of the adjacent rocks cemented together in a conglomeritic or brecciated form, and secondly, in an altered and redeposited form. Thus, the calcium of the limestones occurs in crystals and masses of carbonate of lime. The silica of the sandstones occurs occasionally as quartz, and commonly as re-formed masses of fine sandstone. The argillaceous matter of the shales and limestones takes the form of stiff glutinous clay; while the rarer constituents of these strata, as fluorine, baryta, give the coloring to the commoner substances, or are attached to them. The earthy filling is also affected in character by the particular strata in which the openings occur. The materials have, more or less, a banded or stratified appearance, running roughly parallel to the walls of the lode. This description applies principally to the lodes having a general direction east and west. The great north and south fissures have a different filling. Thus, the "hell-gallop" vein—the long cross-course that extends from Llanarmon in Yale to Holywell—is filled chiefly with a calcareous clay, which in places becomes a true clay, and in others presents the appearance of great masses of carbonate of lime; and in these substances there are imbedded boulders and splinters of the adjacent rocks. The "pockets," or great cavities, are also similarly filled with clay and carbonate of lime. A good example of the way in which this earthy filling occurs is seen in the workings at the Prince Patrick mine as shown in Figs. 3, 4, and 5. As a rule, the clay occupies the lower part of the cavity and the carbonate of lime the upper part, but there are also inter-stratifications and interlacings. The clay in these cases is of a bluish-brown color, generally less brown than blue in the vicinity of lead ore; and the carbonate of lime is found, first, as pure white crystalline masses containing over 99 per cent of carbonate of lime, and, secondly, as gray compact masses of the same, and less pure.

Throughout portions of these earth materials, are distributed the ores of several useful metals. It is with the ores of lead and zinc, and the contained silver, that we have now principally to do; and these I now proceed to describe.

The common ores of lead, as found in the carboniferous strata of the two counties, are the sulphide and carbonate.

Many examples of the combination of lead with other substances also occur in the district, but more rarely, and not in quantity. These are therefore more of interest to the mineralogical student, or for museum purposes, than important commercially, or for the practical purposes of this paper. I therefore proceed to notice the conditions under which the two common ores just described occur, beginning with galena or blue ore. The east and west lodes, including in this term the lodes ranging N. E. and S. W., and those ranging N. W. and S. E., are much more strongly charged with the ore than are the true lodes running N. and S., or nearly so. In the neighborhood of Holywell, there would seem to be an exception to this rule, but there the N. and S. short lodes are frequently intersected by those running E. and W. Apart from this connection, and away from the points of intersection, the north and south fissures have not supported paying mines.

As the lodes pass upward into the dark fossiliferous limestones, they are usually unproductive of lead ores, but the latter reappear in the grit beds; and they are often accumulated in the flats described as lying at their base and upon the surface of the limestone. This horizon of ore is known as the "lower flat."

The thin dark limestone is also unproductive; but the altered sandstones and cherty beds overlying it are known to be good ore-bearing ground. The ore is also accumulated here in "flats" on the surface of this limestone, as already described—the horizon being known as the "upper flat." This brings us to the summit of the lead-bearing strata of the district.

An apparent exception to the arrangement just described occurs in the case of the Minera lead mine, where ore occurs, more or less, all the way down for a depth of 300 yards or so. This lode, however, is on a line of displacement of the strata, the beds on the south being thrown up about 100 yards higher than those on the north. Thus, productive beds have been thrown up against unproductive beds, the result being that, stratigraphically, there is little ground quite unproductive of ore vertically; only, as in similar cases in Yorkshire, there are different degrees of productiveness, according to the kind of strata thus thrown opposite to each other. Then, in the vicinity of a great line of displacement like this, the strata have been much broken, the result being many side-cracks and tributary lodes.

On a lesser scale than Minera, all the great mines that have been worked on east and west lodes have been on lines of displacement. The displacement has usually been an upthrow to the south; consequently the lodes hade or incline to the north, and, on the surface, the limestone beds are seen extending farther to the east, to the south of such lines, as a glance at the geological survey maps of the district will show. It is along these lines, which are usually marked on the surface by hollows or depressions in the limestone belt, that the great mines have been worked. It is seldom that a simple fracture of shrinkage has contained sufficient ore to pay for working for long together.

In these east and west lodes, the ore is arranged roughly in layers, alternately with the carbonate of lime; which layers are more productive, generally speaking, as they approach the heading or lower side of the lode. The layers of ore are not always continuous, and then the ore has a bunchy and nuggety appearance. Many of the minor lodes have a tendency to become pinched and poor in metallic ores as they are followed eastward—a fact that has helped to form the current idea that the farther the lodes run from the great north and south cross-course the poorer they are. The branch lodes that run down from the heading side of the lodes also die out, and become unproductive in depth, except in cases where they are continuous to a parallel lode of any considerable size. The branch lodes or fliers that come down on the hanging side are often productive in the usual productive beds.

There are accumulations of galena in flats that have been formed at the junction of two dissimilar rocks, as at the Fron Fawnog mines, Fig. 1. But productive ore "flats" of this kind only occur where a lode, more or less productive, comes down upon the point from productive ground.

The same remark is true where cavities or pockets, locally known as flats, like those in Fig. 5, contain ore. Such cavities occur along the line of cracks, and one or more may generally be found leading down to them, as shown in the Figs. 3 and 4. This is a fact that is taken advantage of by the miners, who generally contrive to sink their shafts along the line of a crack, which accounts for the tortuous course of many of the shafts in Flintshire. The ore, when it occurs in these flats, is found in rounded masses, from a very small size to lumps of several hundredweights. It is generally of a darker color, coarser grained, and more flaky than the ore obtained from the east and west lodes, and the surface of the lumps is generally a carbonate of lead for a little distance in. It occurs in "runs," or accumulations of such lumps as shown in Fig. 5, such runs being sometimes single separate courses of ore, as in Fig. 3, and sometimes connected by cross or horizontal runs, as in Fig. 4. These runs occur usually in the clay, sometimes in clay and the compact impure carbonate of lime combined, but never in the masses of pure white crystalline carbonate.

In the North Hendre flat lode, Fig. 2, such runs also are found imbedded in the clay, and separated by patches of barren ground.

Carbonate of Lead.—Carbonate of lead, or gray ore, has been raised extensively in Flintshire as far back as our records of mining extend. It is found in the clay that fills the pockets and flats, and, to a lesser extent, in true lodes with a partial clay filling. It varies in color from white to gray and black; and it occurs in concretions and nests in the midst of the clay; for the most part in the lower part of a pocket. It follows the course of the underlying limestone, and is found accumulated in the hollows of its surface, and nestling behind great boulders of limestone.

A pocket now worked at the Queen of the Mountain mine, Halkyn, as represented in Fig. 6, illustrates the usual mode of its occurrence.

These deposits of carbonate of lead, when followed to the solid limestone, frequently change into sulphide in the cracks and fissures leading from the pockets.

Zinc.—Closely associated with the ores of lead in various mines within the two counties are the ores of zinc. The two principal ores, and those of the most commercial importance, are blende and calamine.

The most plentiful of these two ores is the sulphide of zinc. It does not occur with the lead found in the pockets and cavities charged with clay, but it has been found abundantly in lodes in the chert beds above the limestone.

Its chief home is with the lead ores in true lodes in the ore-bearing limestones. It is also obtained from the same lodes in the lowest limestones; but it is neither so plentiful nor of such richness in metallic zinc as when found in the limestones above. The same remarks are true of the carbonate. This ore is, however, found abundantly in parts of the lowest limestones; and at the present time, considerable quantities are obtained from the lodes worked in these beds at the Park mines, south

Digitized by Google

of Minera. In the lodes, the zinc ores occur usually on the upper side of the lodes, overlying the sulphide of lead, as shown in Fig. 7. The ores also occur occasionally in the midst of decomposed portions of the strata, like the deposits of the same ores at Vieille Montagne, in Belgium.

The proportion of zinc ores to those of lead has been very uniform over a long series of years—the quantity of zinc raised being about three fourths that of lead. Being of less specific gravity, and not occurring in the clay pockets or flats, it will be seen that in bulk the zinc ores must more largely fill the east and west lodes than do the ores of lead.

Silver is intimately mixed with the ores of lead, more particularly the sulphide, in the two counties, the proportion in which it occurs, as spread over the whole of the lead raised being 4½ ounces to the ton of ore, and 7 ounces to the ton of lead.

The bulk of the silver is, however, obtained from the ores raised from the east and west lodes. The ores found in the N. and S. cross-courses are very poor in silver; so, also, are those obtained from the flats or pockets in which the matrix is clay, the proportion in these cases seldom exceeding three ounces to the ton of ore. It is also found that lead ores, when associated with blende, are most productive of silver. For example, during the four years ended December, 1878, at the Minera mines, 8645 tons of blende have been raised, along with 8633 tons of metallic lead, and the proportion of silver has been 6¼ ounces to the ton of lead; while at Talargoch mine, during the same period, 8836 tons of blende have been raised, along with 3461 tons of metallic lead, and the proportion of silver has been 9½ ounces to the ton of lead. The same remarks hold good concerning the lead ore raised from the lower Silurian strata. The mines whose ores yield the largest proportion of silver are those which produce the largest quantities of blende.

The Minera Mine—Fig. 8—is worked on the course of a great fault in the limestone and millstone grit strata. This fault also enters the Coal Measures, thus showing that the filling of the crack, with its metalliferous contents of lead and zinc ores, took place at a period subsequent to the deposition of the coal strata. The amount of the displacement, about 300 feet, has had the effect of bringing non-productive beds opposite the beds usually productive of ores, and hence the lode is productive throughout the greater part of its depth, being most productive where favorable strata are just opposite each other. This great dislocation has also had the effect of breaking the strata in its vicinity. Hence there are several subsidiary cracks, which, perpendicularly, run both roughly parallel to, and slightly divergent from, the main fissure. Longitudinally, these cracks start from the main lode, and at some distance come into it again. the ore being usually most plentiful near the junctions, and in those parts of their course where the cracks are widest. Sometimes these cracks die out as they enter the limestone, and in this case the ore dies out also, as it recedes farther from the main lode.

The workings extend along the lode in its course from S.W. to N.E.—at right angles to the section—for nearly a mile in length, the greatest gap occurring where the non-productive beds of the section 5 come to the surface. The lode has now been worked to a depth of 290 yards. Besides the workings on the lode proper, a great deal of lead ore was formerly obtained in and near the limestone beds in the millstone grit *x*, *x*, of the section as they occur in the high ground near the left hand of the section. The lead contains at present an average of twelve ounces of silver to the ton, which is higher than the average of a few years ago, as already referred to.

(TO BE CONTINUED.)

THE STRENGTH OF CORRUGATED BOILER-FLUES.

English and continental engineering circles have, for more than a year, been treating on the subject of corrugated boiler-flues, but little has been said concerning them here, because they were not in our markets. We learn now that Messrs. Hartmann, le Doux & Maecker, No. 184 Pearl street, this city, have been appointed agents of the English inventors, and it may be appropriate, therefore, to put on record the text of a report made by Mr. William Parker, Chief Engineer-Surveyor to Lloyd's Register of British and Foreign Shipping:

"In accordance with the instructions contained in your letter of the 23d inst., I proceeded to Leeds to attend a test to destruction of a rolled corrugated flue or furnace, for the purpose of obtaining some further information on the strength of such structures.

"Several previous experiments have been made to ascertain the strength of these furnaces, as compared with plain ones of the same diameter and thickness, and, although the corrugated flues then experimented upon were not truly round, they showed such a decided excess of strength over plain furnaces that it was considered that a pressure of at least 25 per cent over that allowed for plain flues could be safely permitted for them. The method of manufacture until recently adopted with these furnaces was to form a plain cylindrical furnace, and then produce the corrugations by hammering it between large swages. By this process, it was exceedingly difficult to insure the furnaces being truly round when finished, and this materially weakened the furnaces, as any deviation from the circular form necessarily causes a loss of strength. In order to obviate this result, and also to provide adequately for the increased demand for corrugated furnaces, the Leeds Forge Company has recently laid down a large rolling-mill for the manufacture of the flues. By this method, they are made perfectly true, and must, therefore, be stronger than those made by the original process. The experiment conducted on Friday last was intended to show the extent of this superiority.

"The experimental furnace was 6 feet 9 inches long, 3 feet 1⅞ inches outside diameter, had 18 corrugations 1½ inches deep, and pitched 6 inches apart from center to center of each corrugation. The material composing the flue was mild steel, which was shown by the testing of a piece cut from the plate to have a tenacity of 22·7 tons per square inch, with an elongation of 35 per cent in a length of 10 inches. The furnace was inclosed in a strong wrought-iron cylinder, specially made for the purpose, the annular space between the furnace and cylinder was filled with water, and by means of an hydraulic pump the requisite pressure was applied. Two of Messrs. Dewrance's large pressure-gauges were attached to the cylinder, to indicate the pressure exerted on the furnace.

"Before any pressure was applied, the furnace was carefully gauged for roundness, and it was found to be perfectly true along its whole length.

"The pressure was then applied, and at each increment of 100 pounds per square inch the furnace was carefully gauged, both vertically and horizontally, at the central corrugation, and the third one from each end, and also longitudinally, so that the elongation under various pressures, the limit of elasticity of the material, and the ultimate strength to resist the collapse, should be ascertained. As will be seen from the attached table of results, up to a pressure of 500 pounds per square inch, no alteration in the cylindrical form of the furnace was perceptible, but it had slightly elongated even from the first application of 100 pounds pressure; at 800 pounds, it had sprung or altered its circular form to the extent of $\frac{1}{16}$ inch, while it had gone on steadily elongating to fully $\frac{1}{16}$ inch; but on the pressure being released, it entirely recovered its original shape; at 850 pounds pressure, its alteration was slightly increased, and on relieving the pressure, permanent set could be distinctly measured, both cylindrically and longitudinally, and, at a pressure of 900 pounds per square inch, it slowly collapsed, altering its form more rapidly than could be followed up by the pump.

"After this, twelve holes were drilled at various parts of the furnace, to ascertain the actual thickness of the plate, and the various places showed thicknesses varying from ·51 to ·53 of an inch.

"This experiment shows that the ultimate crushing strength of the furnace could be expressed by the formula:

$$\frac{60{,}000 \times t}{d}$$

where t is the thickness of the plate and d the mean diameter of furnace.

"As the result of this and previous experiments, I would respectfully submit for the consideration of the committee that, for the future, corrugated furnaces (1½ inches deep) should be approved of for a working pressure found by the following formula:

$$\text{Working pressure} = \frac{1000 \times (T - 2)}{D}$$

where T is the thickness of the plate in sixteenths of an inch, and D the greatest diameter of the furnace in inches.

"If this rule is adopted, new furnaces of $\frac{9}{16}$, $\frac{8}{16}$, $\frac{7}{16}$, and $\frac{6}{16}$ of an inch in thickness will possess margins of safety of 5, 5·17, 5·45, and 5·62 respectively, while the same furnaces, when their thickness is reduced by corrosion by ⅛ inch, will in each case possess a margin of strength of 3·9.

"The introduction of the term $(T - 2)$ in the numerator practically provides for the fact that an equal amount of corrosion weakens a structure composed of thick plates to a less extent than it does one made of thin plates. This is already provided for in the society's rules on the shell and combustion chamber plating of boilers, and should apply also to furnaces.

"I may state that at this experiment I was met by Mr. A. C. Kirk, of the firm of R. Napier & Sons, and by representatives from the Admiralty and from the Board of Trade, who were all satisfied as to the value of this experiment in arriving at a satisfactory formula for corrugated flues. I am, sir, your obedient servant, WILLIAM PARKER.

"The Secretary, Lloyd's Registry."

Tensile stress of material, 22·77 tons per square inch.
Elongation in 10 inches, 35 per cent.

LUMINOUS JEWELS.—M. Gaston Trouvé, the well-known electrician of Paris, has lately designed a series of ornaments for ladies' wear consisting of glass, colored and cut to imitate rubies, diamonds, etc., fitted in an envelope, surrounding a small incandescent lamp of low resistance. The light shines through the pieces of glass only, and gives them all the appearance of the stone they are intended to imitate. The lamp is fed from a small battery, which is carried about the person. It is composed of three pairs of zinc-carbon plates (two carbons to each zinc), or a larger number according to the current required. These plates dip in a saturated solution of bichromate of potash, which is contained in an ebonite cell with three compartments. The plates are fitted into a cover, which is kept securely down on the top of the cell by two bands of India rubber passed around the whole. Finally, the battery is incased in two sheets of gutta-percha, so as to prevent any leakage. A miniature switch is carried in the pocket or elsewhere within reach, to which the battery and lamp wires are connected. The pressure of a finger on the arm of this switch makes or breaks communication with the lamp. The battery weighs (with six plates) 300 grams, and will work about 30 minutes with a lamp of from two to three volts. A larger battery, to work a four or eight-volt lamp weighs 800 grams.

FURNACE, MILL, AND FACTORY.

The Montreal *Herald* says: The deputation—headed by two Cincinnati gentlemen—who waited on Sir Leonard Tilley, at Toronto, to urge upon him legislation in aid of the establishment of works for the manufacture of pig and bar-iron demanded a government bonus, amounting to $6 a ton on pig-iron and $18 on wrought-iron or merchant bar. They allege that, if this degree of protection be granted, the parties whom they represent will invest two millions of dollars in works at Toronto and give employment to from 2500 to 3000 men. An account of this interview states that "Sir Leonard said that of course he could make no definite statement as to what the Dominion government might do, but would bring the whole matter before his colleagues for consideration. And at last, whatever was proposed would have to be passed upon by Parliament. One thing he pointed out, that no concession would be made in favor of any particular company only—whatever change was adopted would have to apply to all competitors alike. This the American gentlemen said they perfectly understood." The Toronto *World* believes that Canadian ore can be laid down at the furnaces for from $2 to $2.50 per ton, or one half of what it costs laid down say at the furnaces of Pennsylvania or Ohio. It is admitted that labor would cost nearly the same in both countries, whatever difference there is being in favor of Canada, but that the American iron-works secure their coke at from three to four dollars per ton less than it can be obtained for in Canada. This may be so in Toronto; but if iron-works be established in the vicinity of the coal mines of Nova Scotia, where iron ore of every variety is to be procured, coke can be had as cheaply as anywhere in the United States. It is very unlikely indeed that the Dominion will allow itself to be saddled with a fancy tariff on iron, in order to force the growth of works at points as far removed as possible from the coal-fields of the Dominion. The proposal to import coke from the United States at $8.10 per ton to manufacture iron in Canada is sufficient to show the hollowness of the whole movement. The attitude of those Cincinnati gentlemen, and especially the extravagant bonuses they demand, looks a good deal like an attempt to prevent the establishment of the manufacture of iron in Canada.

The Lechner Manufacturing Company, Columbus, Ohio, has furnished the Holly Manufacturing Company, Lockport, N. Y.; Dupee & Bowman, Forest, Ohio; Woodlawn Mill Company, Woodlawn, Kan.; Cairo Box and Basket Factory, Cairo, Ill., with roller detachable chains for driving purposes. In addition to this, it has furnished G. A. Granger, New Lexington, Ohio, and Ingram Brothers, New Brighton, Pa., with chain elevators.

The Iron City Forging Company, Limited, composed of J. E. Morrison, J. H. Brice, and W. I. Chaffey, recently organized, has erected machine forging works at Summer Station, West Penn Railroad, and they are equiped with every thing necessary for railroad and steamboat forging.

The Newcastle *News* a day or two ago had an item stating that the Rosena furnace had made during the month of November 2913 tons of iron, and that it was probable that this was the largest output ever made in the Shenango Valley. Raney & Berger, however, step to the front with the statement that during the month of November their furnace made 3255 tons, or an average of 108 tons per day. This, it is said, beats any thing ever turned out in the valley.

The Chartiers Iron and Steel Company, Limited, office 143 Fulton avenue, Pittsburg, has recently organized, with a capital of $60,000. The company is composed of John C. Kirkpatrick, Chairman; D. A. Carter, Secretary; B. C. Wilson, Treasurer; and John Henry, Superintendent. It is erecting works at Mansfield Valley, some six miles out the Pan-Handle Railroad, for the manufacture of fine sheet-iron and sheet-steel, and expects to be in operation next April.

The Springfield Iron Company, of Springfield, has been filling an order recently for some very large steel plates. Among others, were one size 228 inches long, 75 inches wide, and ¾ inch thick. The ingots from which these plates were rolled weighed about 6000 pounds.

The Cleveland Crucible-Steel-Works have been bought by Daniel McGarry, and a company, composed in part of the late owners, has organized into the Cleveland Steel Company, to manufacture the same class of goods as at present. The works started up last week.

The Wistar furnace, in Harrisburg, has been sold for $100,000 to the Reading Railroad Company, which will take possession January 1st, 1884.

Stockholders of the bankrupt Danville Steel Company have agreed to transfer the plant to a new company to be at once organized.

The plate-mill attached to the Bailey Nail-Works, in Harrisburg, has shut down, and about 150 men are thrown out of employment. A scarcity of work is the cause.

The Crescent Steel-Works are to have a new melting-furnace, which will be the largest and most complete furnace in the country.

The holiday issue of the *Iron Era*, of Dover, N. J., contains the following: Although business is quite dull just at present with the Atlantic Dynamite and Judson Powder companies at McCainsville, yet the year just closing has been a successful one with them, and they have manufactured a larger amount this year than ever before. It is estimated that the output of the two companies for the year will reach fully four and a half million pounds of powder—or 22,500 tons—as the monthly product has always been above 350,000 pounds. Of this amount, the Atlantic Company manufactures in the proportion of 200,000 pounds to 150,000 pounds for the Judson. About 80 hands and immense quantities of chemicals are employed in making the detonents. The Atlantic Company was the first to manufacture dynamite east of the Rocky Mountains, and its growth has been steady. The success of the Judson powder has been really wonderful, as the company was only organized in 1880. From the time it was first introduced as a low and cheap explosive, its progress has been very rapid, until it is now used on the largest works in the country.

A dispatch from Toledo, Ohio, says that, in the case of the Brown, Bonnell & Co. receivership in the United States Court, claims to the amount of $1,301,000 have been proved upon the order for sale and general distribution. But certain creditors procured a confession of judgment for $540,000, and their attorney went to Cleveland and paid off the original judgment of $51,000. He thereupon asked that the proceedings be discontinued and the receiver discharged. Judge Baxter has announced his decision that the property should be held in trust for all the creditors alike, none of whom would be discriminated against by the judgment creditors in the State courts, and that if they undertook to disturb the property of the company under the judgments obtained at Youngstown, he would enjoin them.

The Western Nail Association decided to close down for a period of six weeks, from December 29th. The meeting at Pittsburg was one of the largest ever held, every mill West being represented.

The Norway Iron-Works, at South Boston, have been sold to a company at the head of which is George P. King. The business will be conducted under the title of the Norway Steel and Iron-Works. The price paid is said to be $150,000.

The workmen of the Edgar Thomson Steel Company, at Pittsburg, having accepted the reduction of 18 per cent in their wages, the mills are running as usual, and steady work is promised to 3000 men through the winter. To the steel men, this reduction means a cut in the wages at all the steel rail mills of the country.

The Penn Iron-Works, of Lancaster, Pa., have shut down until after the holidays, thereby throwing 175 hands out of employment. The suspension is likely to prove permanent, as the men refuse to accept the contemplated reduction in wages.

The Maiden Creek Iron Company's rolling-mill, at Blandon, Pa., shut down December 18th for an indefinite period, in consequence of the dull trade.

The Morris & Cumings Dredging Company, of New York City, will ship to Brazil the largest dredging-machine ever constructed in this country. The company has just finished the canal from Cronstadt to St. Petersburg, and as a result of that work the Brazilian government ordered this machine.

The Bessemer Steel-Works, Pueblo, Colo., turned out 600 tons of steel ingots during the week ended December 15th.

The creditors of the Danville Steel Company have held a meeting in Philadelphia and organized a new company under the Limited Liability Act of 1874. It was organized with the intention of taking the Danville Steel-Works, but this will depend on a proper conveyance being made by the Danville Steel Company, and on the action of the remaining creditors of the company. Steps, however, are taken to carry out the action of the stockholders of the old company. The new company will be known by the title of Grove, Grier & Co., Limited. A capital stock of $83,000 has already been subscribed. This will be increased to $100,000. A Board of Managers has been elected, consisting of Messrs. R. M. Grove, James Cruikshank, and L. K. Rishel, of Danville, and E. Samuel and William Selfridge, of Philadelphia. The officers of the Board are, R. M. Grove, Chairman; L. X. Grier, Vice-Chairman; William Selfridge, Secretary and Treasurer.

A reduction of 10 per cent, without notice, was made in the wages of the laborers at the New Jersey Steel and Iron-Works, Trenton, December 20th.

Nearly all the iron mills in Pittsburg are making arrangements for the usual shut-down during the holidays. Most of them will cease on Saturday, and remain closed until the first week in January, while a few will shut down only to Tuesday next and run the remainder of the week.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY—TOMBSTONE DISTRICT.

Much has been accomplished in the mines during the past week, says the Tombstone *Epitaph*. The Contention pumps have been completed, new hoisting machinery has been erected in three different mines, and assessment-work is doing on nearly every claim in the district. The ore output and bullion production have markedly increased during the past few weeks.

EMPIRE.—The whim of the new shaft is completed, and sinking is again resumed. Lately, the ledge in the new shaft has shown mineralization, and assays as high as $15 in silver have been obtained. In the old workings, prospecting in the direction of the ore-body in the Girard is pushed vigorously ahead, there being little doubt that the ore-body extends into the Empire.

GRAND CENTRAL.—The main shaft is down 30 feet below the water-level. Pumping will not be commenced until the Contention shaft has reached the same depth, which will be in about ten days. After this, both mines will work in sympathy with each other, it being necessary that both keep the same level. In the stopes, every thing is progressing as usual. No new developments have been made lately. The shipment of the usual quantity of ore to the mill is kept up.

MAMMOTH.—Work is going on steadily. The underground workings are connected with those of the Rattlesnake and Bunker Hill, both owned by the same company. The last reported strike of a new ore-body in the Mammoth is gaining in importance every day. It is worked day and night, and no decrease has been noticed.

SIDNEY.—Work has been suspended for the present, owing to some disagreement among the stockholders. The location of this property is adjoining the Grand Central.

TOMBSTONE.—Underground, every thing looks very favorable. The increased output compels the company to stop buying ore as it formerly did, the company's smelting capacity being hardly sufficient to treat the ore produced from the West Side mine.

MOHAVE COUNTY.

MCCRACKEN.—Active operations are to be resumed at this mine, after a three years' stand-still. The twenty-stamp mill is getting into working order, and development at the mine will be pushed vigorously.

PIMA COUNTY.

QUIJATOA.—These mines, the sale of which we reported in the last number of the JOURNAL, embrace the Peerless group, and comprise the Peer, Peerless, Ibex, Shield, Wide West, and Cholla, six claims in compact form—1800 wide by 3000 feet in length. There are several other adjoining claims that are very promising. The Crocker and Mountain Goat are continuations of the Peerless mine. The former is said to be a promising prospect, and high-grade ore has been found on the main lode. On the west side of the mountain, is the Cholla, Wadsworth, and Josh Billings, promising silver prospects, and the Wedge, Emerald, and Murray copper mines.

PINAL COUNTY.

SILVER KING.—The company has now at Casa Grande the machinery for well-boring, and is going to sink a 12-inch well in the mill. Besides the Queen Creek flow, it has a 6-inch well, 150 feet deep. The drill will go through the volcanic rock, and will probably find abundant artesian water.

CALIFORNIA.

INYO COUNTY.

MAXIM.—This company, which is said to be composed of New York capitalists, some two months ago purchased the Arasta mine, which has since been worked. The Inyo *Independent* says that the mine was worked to a limited extent some seventeen years ago. The shaft which is now sinking has attained a depth of forty feet, and a three-foot ledge of rich ore has been struck. The necessary machinery has been bought, and is now on its way to the mine.

MONO COUNTY.

MAY LUNDY.—Considerable activity prevails in and about this mine, and the force is engaged in extracting ore. The mill is running full capacity, with over 700 tons of ore in the yard. Nothing positive has yet been learned of the rumored sale of this mine to English capitalists.

BODIE DISTRICT.

BODIE CONSOLIDATED.—The official report for the week ended December 8th shows: Ore crushed, 145 tons; average assay value of pulp, $24.45 per ton; of tailings, $4.90 per ton. There were 190 car-loads of ore hoisted from the mine—13 car-loads of which were from the 770 (shaft) level, and 177 car-loads were extracted from the 640 to the 780 levels.

STANDARD CONSOLIDATED.—There is no change of importance to note. The official report for the week ended December 8th shows: Ore extracted and shipped to mills, 1296 tons; crude bullion received, 2130 ounces; bullion shipped, $10,998.60.

SIERRA COUNTY.

ALASKA.—The work of raising the water from this mine has been resumed, and it is expected that the mine will soon be in full operation.

COLUMBO.—This claim is located west of the Sierra Buttes mine. From an adit-level which has cut the vein some 225 feet below the surface, a very rich class of ore is exposed, showing free gold in abundance, and giving satisfactory results. This mine was purchased some months ago by Eastern capitalists, who propose to erect extensive machinery and thoroughly develop the mine.

RUBY.—This gravel mine has produced its first bullion.

SOUTH FORK.—This mine continues to yield handsome returns to its leasers, the Bald Mountain Extension Company. From 427 car-loads of gravel, ninety

Digitized by Google

and a half ounces of gold were cleaned up. The pump at the Pliocene shaft has been started up. The Extension Company has let a contract for running ahead the main tunnel 400 feet, at $3.75 a foot.

CANADA.

PROVINCE OF NOVA SCOTIA.

There has been little excitement in gold mining in Nova Scotia this season. The usual tribute-work has been carried on, and several individuals have made good profits. Among the companies that have been working with steady returns may be mentioned the Strawberry Hill, Oxford, Salmon River, and Gallagher mines.

The Oxford mine shows, since August, 1882, a return of 1538 tons, yielding 2775 ounces. The Salmon River mill, since August, 1881, has crushed 11,974 tons, yielding 9531 ounces. The Gallagher mines, at Isaac's Harbor, have been very successful since they started in the spring of 1883. There have been 962 tons crushed by them, and a yield of 2413 ounces secured.

The only new district that promises well at present is the Bridgewater, where a large tract of auriferous ground has been proved. The prospectors are making arrangements to put up a mill, and, should the locality pan out well, gold mining west of Halifax will receive a fresh start.

COLORADO.

CHAFFEE COUNTY.

ALPINE.—Owing to the lack of ore, the smelter has been idle for a short time. The intention of the managers however, is to start up the blast-furnace not later than the end of December.

HORTENSE.—There are two car-loads of ore ready for shipment which will, it is estimated, run $100 to the ton. Work is progressing at present on the winze between the fourth and fifth levels, which shows about five inches of 101 ounce ore. Samples of the ore sorted from all parts of the mine gave a return of sixty ounces in silver and 1·15 ounces in gold. The ore in sight will probably average $75 to the ton The fifth level, now in 147 feet, will be driven ahead, and it is thought will strike the ore-body at about 175 feet. When the winze to this level is completed, the mine will be in good shape for back-stoping and hoisting the ore. The lessees who now have the mine have done a large amount of dead-work in the way of cleaning out the levels, removing waste dirt, etc. From this time on, however, until the expiration of their lease in August, systematic development will be made.

CLEAR CREEK COUNTY.

A discovery of a rich gold-bearing vein, just off the Whitlow Survey, on Soda Creek, has been made which, it is thought, in richness will eclipse the Whitlow, Golden Leaf, or Golden Dustman lodes. Pan prospects go very high.

CENTENNIAL.—This lode in Hukill Gulch, Spanish Bar District, shows well. A drift has been run on the lode 120 feet, and at the breast a shaft sunk 11 feet, in which is exposed a streak of solid mineral eight inches wide. It is a galena ore in which are largely intermingled gray copper and black oxide of copper, resembling very much the rich pockets of the Hukill mine.

NEW YORK & COLORADO.—The new and large mill of this company, which is located in Germantown, three miles west of Empire, has been finished, and the mill opened for operations.

WISCONSIN & MOORE LODES.—Recently, while the work of driving the main tunnel on these lodes was progressing, a large and well-defined crevice, carrying a body of decomposed ore, was encountered. A test made at the Rocky Mountain mill gave twenty-two ounces silver per ton. This crevice was struck about 250 feet from the mouth of the tunnel.

GILPIN COUNTY.

UNION & BONANZA.—The tunnels are driving night and day. The Bonanza is now in under Maryland Mountain a distance of 1120 feet. In driving it 120 feet farther, the Robert Emmett mine will be intersected. Several levels are driving east on different veins that have been tapped by the tunnel workings. One vein, which is thought to be the easterly extension of the Cyclops, is turning out a very good quality of smelting ore.

GUNNISON COUNTY.

An important sale of five gold placers has been consummated. The property embraces 147 acres of ground in Taylor Park, thirteen miles north of Tin Cup. The consideration was $10,000. From the work so far done on the property, it promises to become one of the heaviest gold producers in that district.

LAKE COUNTY.

ARKANSAS VALLEY SMELTING COMPANY.—Dr. D. H. Dougan, the present manager of this company, will retire from the management of this company's works here in Leadville on January first. Dr. Dougan has been in charge of the Arkansas Valley Smelter for about six months past. Mr. Charles T. Limburg, the former manager, is mentioned as Dr. Dougan's probable successor.

BRIAN BORU.—The Kearney lease on this mine is meeting all the expectations of its sanguine owners. The mine at present is employing eighteen men and shipping ten tons of ore a day. This shipment will soon be doubled. The mine is looking very well, and discloses some very large bodies of magnificent galena sand and hard carbonates.

HUMBOLDT.—The lessees on the Thistle mine, on Carbonate Hill, one of the properties of this company, have disclosed a streak of ore, and the dump at the shaft shows about a ton of mineral. The value of the new discovery has not yet been ascertained.

IOWA GULCH.—The Scooper, the property of this company, shows two feet of ore of extraordinary grade. The manager stated that the mine was leased about four months ago, and since then a force has been employed in exploration-work. The most favorable indication of mineral was along the walls of the porphyry dike, and prospect-work was advanced in this direction. The point at which operations were begun was a short distance northeast of the shaft, and a trifling depth below the first level. After driving work for some time, seams of galena ore in an iron matrix were encountered, and being closely followed, these stringers of ore gradually led to a well-defined vein of pay mineral, which at the present time discloses from twenty to thirty inches of ore. That the new discovery promises to result in more than a single small pocket, is demonstrated by the development of apparently the same ore-body at another point, twenty feet distant. In addition to these developments, a small quantity of ore has been opened in still another place. The ore developed in the larger streak, the reporter is informed by responsible parties, has been assayed a number of times, and has returned from 1500 to 2000 ounces to the ton, being very rich in chlorides. The value of the ore when shipped in large lots is still unknown, but will be determined shortly.

IRON HILL CONSOLIDATED.—This company has reduced the wages paid to trammers and surface laborers to two dollars and a half per day.

SIERRA NEVADA.—This claim is situated on the southeast slope of Iron Hill, adjoining the Colonel Sellers mine. The favorable location of the claim attracted the attention of a number of gentlemen several months ago, and shortly afterward they formed a pool with the view of developing the same. Operations were begun immediately and pushed with such vigor that at the present time the shaft has a depth of 247 feet. The ore zone, it is expected, will be encountered at a depth of about three hundred feet, which, it is calculated, will be reached by January first next. The owners of the Colonel Sellers mine have already driven a drift to near the line of the Sierra Nevada, disclosing good ore, and the projectors of the new enterprise are reasonably certain of the mineral extending into their territory. A twenty-horse-power hoisting-engine and other improvements have been placed on the property.

SILVER CORD.—The company has purchased a controlling interest in a portion of the Ruby mine. The consideration in the deed is stated at $150,000, but the actual amount paid was only $48,500. The portion of the Ruby in which the Cord has secured a three-fourths interest is a trifle over half of the southern part of the claim, being about 164 feet. The Silver Cord Company would probably have purchased the entire claim, but was prohibited from doing so by a compact made with the Iron Silver Company some time ago. When the conflicts between the Iron Silver and Silver Cord companies were settled, a compromise line was established, which was designed to limit the further acquisition of territory that might possibly reopen the conflicts adjusted. The line was particularly desired as fixing the boundaries between the two mines, as they advanced on the vein beyond their side-lines and into adjacent ground. The Iron Silver Company has since extended its development well into neighboring claims, and has attempted to secure the ore under the statutes permitting the owners of the apex of a vein to follow it beyond their side-lines. The Silver Cord, on the other hand, has from time to time purchased portions of other territory to the rear of the outcrop, until it has acquired over sixty acres of ground. Its recent purchase of the Ruby completes the acquirement of new territory, as the Cord now owns all the territory for fifteen hundred feet, back of the claims located parallel with the outcrop of the vein. The purchase of this piece of ground, it is believed, will give the Silver Cord a considerable distance of the ore-chute, that heretofore was outside of its territory.

PITKIN COUNTY.

Encouraging reports comes from the Tellurium District, which is about twelve miles on a straight line northeast of Ashcroft, and comprises Jordan's, Old Man's, and Tellurium gulches, near the head of Taylor Park.

The most prominent mine in the section is the Lavicy A. The vein is a quartz porphyry vein in granite, carrying sulphurets of silver running from $180 to $2400 to the ton. The developments of the mine consist of a shaft 170 feet in depth, with a level 140 feet in length at 40 feet from the surface, and another 120 feet long at 120 feet from the surface, also a rise from the end of the lower level to the surface, making another 120 feet. Eighteen men are employed on the property, and a considerable amount of ore is extracted and shipped to the St. Elmo smelting-works.

In Jordan's Gulch, is the Nellie H. claim, located in an eight-foot vein in granite, showing a two-foot pay-streak of quartz, from which mill-runs have been obtained, returning 127 ounces in silver, one and three quarter ounces in gold, and 26 per cent in copper. The property is opened by a tunnel, in 32 feet, and a shaft, down 22 feet.

In Old Man's Gulch, are four claims. The vein is the same as the Nellie H., although three miles distant, and shows some very good mineral.

In Tellurium Gulch, in the old Tellurium tunnel, started in 1859, a force of fourteen men is now working, and some very fine ore is taken out. This vein was discovered in 1859, and the present owners, when they relocated the property in 1880, found three tons of galena ore on the dump. The tunnel shows a fair streak of very highgrade ore.

SAN JUAN COUNTY.

MONTEZUMA.—This tunnel cut the Victoria vein after running 594 feet, and at a depth of 300 feet. The lode shows a five-foot crevice and three feet of solid mineral—gray copper, yellow copper, pyrites of iron, and galena. No mill-runs have yet been had. Work to rise and connect with a shaft sunk thirty feet two years ago will be commenced, which had to be abandoned on account of water. Drifting will also be done. The ore can be taken out and loaded on the car for $2.75 a ton. Work will also be commenced again on the Ajax tunnel, which will cut the Victoria lode 520 feet deeper and 150 feet to the right. This tunnel is now in 340 feet, and 170 feet before the vein is cut.

GEORGIA.

An important strike in the vicinity of Dahlonega has caused considerable excitement. It is believed that the vein discovered is a continuation of the Fish Trap vein. The reports from various other mines in Lumpkin County are of a favorable nature.

DAHO.

The Denver *Tribune* reports that the silver and lead product of this section for the year 1883 will not be less than $2,500,000. The Philadelphia Smelting Company, at Ketchum, has two 50-ton furnaces and one 40-ton furnace. It shipped this year over 3000 tons of bullion, worth over $1,000,000. It shows that it has smelted ore from over ninety mines or prospects, the average value of the same being over 145 ounces silver and 50 per cent lead. The Minnie More mine, at Belleview, and the Elkhorn mine, at or rather near Ketchum, are remarkably strong veins in black lime, and are large producers. The Elkhorn has produced 2200 tons of ore, which assays 125 ounces and 50 per cent lead. The output of the Minnie More, at Belleview, is about 50 tons per day, with an average of 100 ounces silver and 60 per cent lead. The Idahoan, near Bullion, has shipped about 2500 tons; average, 100 ounces and 50 to 60 per cent lead. The Bullion, Mayflower, Eureka, and other mines at Bullion average 150 ounces silver and 60 per cent lead. The Jay Gould, at Bullion, averages 100 ounces silver and 60 per cent lead. The Narrow Gauges mines Nos. 1 and 2, the Davitt, Snow Fly, Montana, and Mount View mines, in Deer Creek, are all producers of mineral, and run at mill from 100 to 150 ounces silver and 50 to 70 per cent lead. The Imperial, in Green Horn Gulch, is a producer of ore that runs from 50 to 60 ounces silver and 50 to 60 per cent lead. It is a very promising-looking prospect. One remarkable thing we found in this district, and that was all of the mines had paid for their purchase money and all developments and improvements. There is in the valley a sampler at Hailey and a smelter at Ketchum. Through these institutions all of the ore passes.

MAINE.

DOUGLAS.—To hear a statement from the treasurer as to the indebtedness of the company; to consider and determine the best means of raising sufficient money to pay the debts of the corporation and for its other needs, and, if deemed advisable, to vote to borrow not exceeding thirty thousand dollars, fixing the time of payment and rate of interest; to vote to mortgage the real estate and other property of the company to secure said payment; and to authorize the treasurer to sign and issue in behalf of the company notes or bonds of the company as may be necessary, not to exceed the limit named, was the business proposed to be transacted at the recent special meeting of stockholders. The result of this meeting has not yet been published. It is stated that the company shipped sixteen tons of refined copper to Boston during the week ended December 15th.

MICHIGAN.

BELT.—Work on the new stamp-mill goes on as rapidly as possible, and is fast drawing to completion. It is hoped that the mill will be started by New Years' Day. The underground work in both mines is pushed ahead as rapidly as possible, and is everywhere looking encouraging. The openings made in the old mine on the Champion vein are quite extensive, and will furnish a large amount of profitable stoping ground. The openings made in the new mine on the Knowlton vein are also reported to be favorable.

CHAPIN.—A force of between four and five hundred miners has been set to work in the Chapin mine, the men re-employed being those who were but passive participants in the recent strike. The force now employed will be increased gradually during the winter, and the mine will doubtless be working as many men by the time another shipping season opens as prior to the strike.

Digitized by Google

MINNESOTA.—The reported sale of this mine to the Earl of Denbigh and other English capitalists has been denied. According to the Marquette *Mining Journal*, the Minnesota stockholders voted to sell the property, and the matter has been laid before some English parties, who are making an investigation of its merits. The stockholders voted to sell the property for $50,000, and an agent has been trying to dispose of it in London for $75,000.

NANAIMO.—A new find of importance has recently been made at this mine, but independent of the old mine. The find is south and west of the old mine, and has been traced by a series of test pits a distance of 200 feet. A belt of jasper 300 feet in width separates the newly discovered deposit from that constituting the lens in which the mine is situated. No cross-cutting has been done as yet to determine the extent of the new discovery, but, from all evidence, it is of large proportions. The ore is of good quality, as regards metallic iron, but a non-Bessemer, as the other ores of the vicinity.

The Marquette *Mining Journal* gives the following analyses of iron ore taken from the new mines of Agogebic, Sunday Lake, and Montreal districts, and which were made by and at the instance of wholly disinterested parties:

Name of mine and location.	Metallic Iron.	Phos.	Silica.
Section 10, town 47, range 45	64·82	·046	6·50
" " " " " "	67 85	·040	1·84

Sec. 1, town 45, range 1, east	65·67	·102	1·65

The Ryan and Montreal mines are across the line in Wisconsin, the others in Michigan. These districts will be supplied with railroad facilities next season, possibly in time to enable some of the mines, to ship a part of their product.

MONTANA.

Mr. L. A. Walker, Assistant-Assayer in charge of the United States Assay-Office at Helena, during the absence of Assayer Harrison, gives the following statement to the *Herald* of the gold and silver received at Helena for the year 1883, and since the establishment of the Assay-Office in 1876:

1883.	Gold.	Silver.
January	$43,618.88	$6,735.69
February	26,821.03	844.51
March	24,535.18	697.04
April	36,611 36	945.87
May	40,489.69	1,117.39
June	74,437.23	6,706.87
July	108,123.57	1,754.48
August	94,154.73	1,033.26
September	93,348.78	1,199.45
October	78,401.36	1,219.77
November	103,750.36	994.93
December (estimated)	49,500.00	500.00
Total	$773,792 17	$23,749.46

Values of gold and silver bullion deposited at the United States Assay-Office, Helena, from January 1st, 1877, to December 31st, 1883:

	Gold.	Silver.
Year ended Dec. 31, 1877	$379,481.18	$241,197.12
" " " " 1878	298,681.77	404,567.98

" " " " 1882	678,925.33	91,013.16
" " " " 1883	773,702.17	23,749.46
Total	$3,709,381.42	$1,132,899.29

JEFFERSON COUNTY.

The railroad has reached Wickes, the last rail being laid a short distance from the smelter, and the company will soon begin the shipment of such ores as can not be worked at Cainet, to the reduction-works of the East.

MADISON COUNTY.

VIRGINIA CITY REDUCTION COMPANY.—These works have started and are running night and day on ore from the Prospect mine.

SILVER BOW COUNTY.

ALICE.—The Salt Lake *Tribune* publishes the following interview, as a reply to the letter recently written to the ENGINEERING AND MINING JOURNAL:

The article was shown to Mr. J. R. Walker, President of the Alice Company, on his return from San Francisco, and he was asked whether the property was skillfully and economically managed. He replied: "The Alice Company is worked as economically as, and perhaps more so than, any other company in the West. I don't except any. The president gets no salary, and all we pay for labor is what goes to the workmen at the mines and mills, a book-keeper, and one assistant-secretary. The management of Superintendent Hall and his assistant, Mr. Daft, has never been questioned, and we are in every way satisfied with it."

"Are the newspaper figures showing the shipments correct?"

"While the figures as given in the *Tribune* and other papers may be approximately correct, based on the shipments of a given month, yet they are not absolutely so, because a part of the product of the preceding month is included in these shipments as reported. The amalgam is on hand, but it takes from eight to ten days to put it in a marketable shape; that is to say, to manufacture it into doré bars. At the end of the year, however, the actual shipments and the newspapers' reported shipments agree, while the monthly shipments as actually made may be reported differently by the papers."

"Is the shipment of $195,836.63 reported as having been made in October correct?"

"According to newspaper figures, it may be correct, but the actual production for that month was $102,346.05 assay value. This netted the company in New York $86,856.23. This discount is due to the difference between the actual market value of the silver in New York and the assay value. All the assayers' tables are based on the standard price of silver being placed at $1.2929 per ounce; and in figuring the value of bullion, the worth of a particular bar is based upon this standard price of silver. But, as you well know, the present market value of bullion is about $1.10 per ounce for fine silver. Our shipments from the Alice, however, are not of fine silver, but consist of bullion, containing silver, some little gold, base metals, consisting of some little lead and some copper, and costs perhaps two cents per gross ounce for refining and separation, so that not only do we not get $1.2929 (on which basis we have to figure here), but we do not even get $1.10, the market price for fine silver."

"I see the disbursements for October are placed at $41,600. Do these figures include your entire disbursements for that month?"

"No, sir; those figures represent simply an estimate of the funds required by the superintendent for the payment of labor, ore extraction, reduction, prospecting, and dead-work, mine and mill improvements, freight, some lumber, and a few local bills at Butte. It does not include the cost of salt, wood, oils, quicksilver, expressage on bullion, and a hundred other things necessary for the running of so large a mass of machinery and such extensive mines as the Alice and Magna Charta are."

"Can you show me the actual receipts and expenses for the year?"

"In about a month from now, say about January 1st, we shall get out a report of the financial condition of the company, and the stockholders can then see for themselves just exactly how the business stands. While we claim to have worked the property as economically as it could possibly have been worked, we do not claim to have made the ore in the mines, and hence have to take it as we find it. Our ore assays from 35 to 50 ounces, and while the statement that 'Stockholder' makes regarding our having produced sixty car-loads of ore a day may be true, yet his information that our ore assays from 150 to 200 ounces is not true, and the ore we are now taking out is not 'better ore than any taken out for years.'"

"Is the company out of debt?"

"By no means. The chief indebtedness we have is that due to the Walker Brothers, for the purchase of the Magna Charta, Valdemere, and other outside lode claims contiguous to the main property. Walker Brothers loaned that money to the company at 4 per cent, a very low rate of interest, and, instead of taking the receipts of the company and applying them to the payment of that debt, the Walker Brothers, as the holders of the majority of the stock, have gone on making improvements for the benefit of the company. This debt due by the Alice Company can easily be discharged if the stockholders so desire; for the Walker Brothers will to-day take back less than one half of the property they sold to the Alice Company and discharge the indebtedness due by the company to them. In other words, they are willing to give the Alice Company more than one half of the property for nothing and take the balance in satisfaction of the debt due by the company to them."

"When will you resume payment of dividends?"

"Dividends will be resumed as soon as the company is out of debt and is able to make a dividend. The last dividend was paid in December, 1881, and since then the product of the property has been used for opening up new ground, sinking two new shafts, and developing further on the old shaft, erecting additional new machinery necessary to work the property acquired from Walker Brothers and also in making partial payments for the properties purchased from Walker Brothers.

"Our reasons for the non-resumption of dividends are as follows: First. The fact that the Utah & Northern has heretofore charged such arbitrary rates on necessary supplies, such as salt, quicksilver, etc., has made our running expenses very high. We expect relief, however, from this source next spring, when we hope to see the Northern Pacific completed into Butte. In addition to this, the cost of fuel has doubled in the past three years, on account of so many mines being opened and the wood having to be hauled double the distance. Other expenditures have increased since then, but it is not necessary to mention them in detail. Secondly. Since the first developments were made in the mine, we have struck a poorer grade of ore, and that has necessarily reduced our income. Thirdly. We have so enlarged the property by purchasing additional mines and extensive and expensive machinery, all of which had to be paid out of our receipts, that our dividend-paying power has been entirely prostrated. Our expenses have also been increased necessarily by the purchase of these properties, and, as in all enterprises of this character, it takes time to realize on the money invested. It will eventually regulate itself, and the property will then show up in its true light.

"Another very pertinent matter in this connection is the fact that most of the large stock companies organized on the Comstock and other places have been run on the assessable plan, whereby stockholders could at any time be called upon to pay for all such improvement as we have made on the Alice. But our company has not only not assessed its stockholders for these improvements, but it has paid for them out of the net earnings, and in addition purchased valuable properties on credit at a nominal rate of interest from parties whose sole aim has been to make the Alice a mining property that should be a credit to Butte and the whole territory of Montana. It has always given us great pleasure to have the residents of Butte and Walkerville, as well as mining men and experts from all parts of the country, visit the property and examine the same. We have never denied admission to the property, and it always has been and is now opened for the inspection of all or any parties who desire to see it and its workings."

COLORADO SMELTING AND MINING COMPANY.—The most important transaction of the past week was the reorganization of the Colorado & Montana Smelting and Mining Company, under the name of the Colorado Smelting and Mining Company. Articles of incorporation have been filed in which the capital stock is placed at $1,000,000, and the following officers named: N. P. Hill, President; W. A. Clark, Vice-President; H. R. Wolcott, Secretary; H. Williams, Manager. In addition to the valuable properties heretofore owned by the Colorado & Montana Company, the new company includes in its list of properties a three-fourths interest in the Basin Flume Company and the Gagnon mine.

NEVADA.

ESMERALDA COUNTY.

NORTHERN BELLE.—Various rumors regarding this company are in circulation. One of them states that the company's checks went to protest in San Francisco recently, and the mine was forthwith attached by the Carson & Colorado Railroad Company. It is stated that the mine will eventually be sold to satisfy the $360,000 judgment, and most likely be bid in by the Holmes Company. Another report states that the company has discharged all its men and shut down the mills. The mine and mills will probably remain closed until the property passes into the hands of the Holmes people, who will probably resume work and prospect for more ore-bodies.

STOREY COUNTY—COMSTOCK LODE.

The greater portion of the big hydraulic pump at the Combination is in position and the work is crowded as rapidly as possible. Owing to the low water in the Carson River, the mills are not running full-time.

ALTA.—The water is out of the mine nearly down to the 2150 level. As the pumps are now drawing the water from about 3000 feet of drifts, progress is at present very slow. The draining of the Alta will allow of work being resumed in the Benton, and the Justice folks will also doubtless resume operations, drifting into their ground from the Alta, as they had arranged to do before the flooding of the latter mine.

CHOLLAR & POTOSI.—With the starting of this pump, work will be resumed on the 2600 level.

UNION CONSOLIDATED.—At the north end, the south drift in the Union Consolidated is out over 70 feet from the joint Sierra Nevada station at the 3100 level. It is in vein porphyry and other vein material which as yet shows no value. The drift is pushed directly for the main drift that is coming north of the same level. The two are nearing each other at the rate of about 70 feet per week. This connection will be quite an event for the north end mines. It will form an air-gallery for the Mexican, Union Consolidated, and Sierra Nevada, from which a new departure may be taken in deep exploration to the east and west.

PENNSYLVANIA.

The Chickies Iron Company has struck a new vein of ore south of the present workings at its Springfield bank. A shaft has been sunk some 40 feet, all in ore, with every indication of its running to a great depth. This company has lowered its plane at the Myers bank, and is now working a 40-foot breast of very rich specular and hematite combined.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Dec. 21.

This week has been one of the dullest in the mining market, and it can not be said that the dealings furnish any items of interest. The transactions were scattered throughout the list, but they were generally very small. Iron Silver was one of the stocks most largely dealt in, and it suffered a slight decline in prices. Northern Belle shows no material change in price from our last, but continues weak. Sutro Tunnel was very actively dealt in, and was a little weak. Sonora was also very active, but remains steady in price. We give a complete summary of the market below. The total number of shares sold aggregates 94,335, as against 120,260 last week.

The Comstock shares were very moderately dealt in at steady prices. California was quiet and steady at 15@16c. Consolidated Virginia was also quiet at steady prices, selling from 30@33c. Sierra Nevada was strong, under a small business, selling from $2.55@$3.50@$3.25. Union Consolidated was quiet and steady, selling from $2.55@$2.80@$2.75. Mexican was very quiet, selling at $1.90 to-day. Sutro Tunnel was very actively dealt in at irregular prices; it sold from 19@15@16c.

The Leadville stocks were quiet and steady. Amie sold from 9@10c., with a small business. Chrysolite was quiet and steady, selling from $1.30@$1.25. Dunkin was irregular, selling from 28@26@27c. Breece sold at 15c. Iron Silver was very actively dealt in, and was weak; it sold from $2.30@$2@$2.05. Leadville was weak, under small business, selling from 50@40@42c. Little Chief was quiet and strong, selling from 56@60c. Little Pittsburg sold from 52@47c. under a small business. Climax was quiet at 7c.

The Bodie stocks were very quiet at steady prices. Bodie Consolidated was strong, with a fair business, selling from 65@75@71c. Standard was quiet and steady, selling from $6@$5.75.

The Tuscarora stocks were almost neglected. Grand Prize was quiet at 25@24c. Navajo sold to the extent of 200 shares at $3.25. Independence sold at 8c.

In the miscellaneous list, Alice sold at $2.60, with one small transaction. Eureka was quiet and steady at $3. Green Mountain was strong, under a moderate business, selling from $1.20@$1.35@$1.30. Homestake was quiet and strong, selling at $12. Horn-Silver was active at steady prices; it sold from $6.13@$6.25. Northern Belle was irregular, selling from 16@25@22c., with a small business. Robinson Consolidated was quiet and steady, selling from 33@30c. Sierra Grande was a little weak, selling from 65@60c., under a small business. Silver King was strong at $7.63. Stormont sold to-day at 15c. Castle Creek was very weak at the opening of the market, but regained some strength at the close; it sold from 8@40c., with a small business.

Barcelona was quiet and a little weak, selling from 22@20c. Central Arizona was steady at 20c., with a small business. Eastern Oregon was very irregular, under a small business; it sold from 12@8@18@15c. Harlem was quiet and a little weak, selling from $1.15@$1.05. Sonora Consolidated was very active at steady prices; it sold from 24@22@23c. North Mexican sold from 80@65c., with a small business. Colorado Central was quiet and steady at 38@39c.

There was considerable excitement in mining circles this week, occasioned by the election of trustees of the Ophir Mining Company, at San Francisco, and the bitterly contested fight between Mr. Flood and Senator Sharon for the control of the company. The following dispatch from San Francisco, giving full details of the contest, will no doubt be of interest:

The election was the most exciting since the great Hale & Norcross fight in 1868, when the shares of that company rose to $8000. The capital stock of the Ophir Company is $10,800,000, in shares of $100 each. The real fight was to obtain possession of the milling ore, in which all the profits lie. Up to this morning, the general belief was, that Senator Sharon would capture the mine. This was strengthened by the known fact that Secretary McCoy, who married Sharon's niece, was going to vote his 1100 proxies for the Sharon interest. At mid-day, the Nevada block was surrounded by an eager crowd, anxious to learn the probable result. The voting commenced at 1.05 P.M. At half-past two o'clock, the vote stood: Flood, 41,714; Morrow, representing the Sharon interest, 2537. Mr. Richardson, of the Bank of California, holding Sharon certificates and proxies, appeared and voted 47,105 shares. This was offset by W. H. Wright, who cast 1460 votes for Flood, giving him the victory with 50,922 votes against Sharon's 48,855. The State law calls for seven trustees. By mutual agreement, four were to be from the winning side. They are C. L. Weller, C. O'Connor, Charles Fish, and R. H. Follis, Sharon's trustees are A. K. P. Harman, Morris Schmidt, and J. H. Robinson. E. C. Holmes was elected secretary. The victory is credited to the energy of J. L. Flood, son of the millionaire. He says the policy of the company will be to continue work on the lower levels, in the hope of finding a new bonanza, and to continue the search as deep as it is possible to go. The secretary's report showed a balance of $6500 on hand on December 18th, deducting all indebtedness. The stock sold to-day at $20 cash: seller ten days, $7.

Senator Sharon's defeat is said to be due to a mistake or to deceit. When the name of Homer O. King, a mining broker, was called, Mr. Morrow produced the firm's proxy for 2665 shares, but the Flood party immediately reduced this to 10, producing 2655 shares of actual stock. Three similar occurrences followed, and this gave Mr. Flood the election. While Senator Sharon held all the proxies, Mr. Flood held solid stock. A later dispatch states that the vote by which Mr. Flood retained control of the Ophir was Flood, 51,580½; Sharon, 49,092.

MEETINGS.

The Bullion Consolidated Mining Company, Room 62, Drexel Building, New York City. Annual meeting of stockholders and election of trustees January 8th, at ten o'clock A.M.

The Ophir Consolidated Mining Company, Room 62, Drexel Building, New York City. Annual meeting of stockholders and election of trustees January 8th, at eleven o'clock A.M.

DIVIDENDS.

The Bonanza King Consolidated Mining Company, of California, has declared a dividend of twenty-five cents per share, payable immediately.

The Contention Mining Company, of Arizona, has declared a dividend of twenty-five cents per share, payable December 24th, at the Farmers' Loan and Trust Company, Nos. 20 and 22 William street, New York City.

The Father de Smet Consolidated Gold Mining Company, of Dakota, has declared dividend No. 30, of twenty cents per share, payable at the office of Laidlaw & Co., No. 14 Wall street, New York, December 31st.

The Hope Mining Company, of Montana, has declared a dividend of $1.50 per share, payable December 31st.

The Ontario Silver Mining Company, of Utah, has declared its 90th dividend, of $75,000, for November, payable at the office of Messrs. Lounsbery & Haggin, No. 15 Broad street, on December 31st. Transfers will close December 24th. The total of dividends to date is $5,150,000.

The Osceola Consolidated Mining Company, of Michigan, has declared a dividend (No. 17), of fifty cents per share, payable December 15th, to stockholders of record.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway, report as follows on oil for the past week:

This has been one of the dullest weeks of the year in the oil market; the extreme range of fluctuations was 2⅛ cents per barrel. The highest price was $1.14⅝ last Saturday, and the lowest was $1.12½ on Wednesday. The approach of the holidays and the dullness that usually accompanies that season has prevented any activity, and many bulls sold their oil to avoid carrying charges. The Boards in Oil City, New York, Pittsburg, and Bradford will close from Saturday, three P.M., until Wednesday, December 26th, at ten A.M.

Carrying rates in this market have been about 70 cents, and this discouraged the bulls and invited some short selling. To-day, Grandin No. 18 was reported 6 feet in the sand and showing for a fairly good well. It is on the southwestern frontier of Balltown, and is important as showing that the Balltown District is not entirely exhausted.

One of the weakening influences of the month has been the excess of runs (or receipts) over shipments (or deliveries), which shows that so far this month there has been an accumulation of oil. During each of the months of August, September, October, and November, the stock of oil was reduced. The best informed oil men, however, believe that unless some new field is discovered this winter that the visible supply of oil will be considerably reduced before spring. Exports this month are on an average 7000 barrels per day larger than in November. The market is expected to be better and higher early in the year for both refined and crude.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Dec. 15.....	$1.14	$1.14⅝	$1.13⅝	$1.13¾	4,093,000
17.....	1.13⅞	1.14⅜	1.13¾	1.13⅞	3,775,000

BULLION MARKET.

NEW YORK, Friday Evening, Dec. 21.

Under higher rates for silver abroad and for sterling exchange here, the figures of the accompanying table show some advance in rates for silver in our market.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
Dec. 15	50 13-16	110⅛	Dec. 19	50⅞	110⅜
17	50⅞	110¼	20	50⅞	110½
18	50⅞	110¼	21	50⅞	110⅜

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

MINES.	States.	Month of November.	Year from Jan. 1st, 1883.
*Alice, G. S.	Mont		$885,934
*Alta-Montana, G. L. S.	"		$10,625

* Official. † Net value. ‡ Assay value. § Not including value of lead. *G. Gold. S. Silver. L. Lead.* The dash (——) indicates that no shipments have been made in the month named. ** Silver valued at $1.10 per ounce.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended December 21st, as compiled from various sources, amounted to $119,000, as against $207,878 reported for the previous week. The receipts from January 1st, 1883, to date are $11,145,321.

Foreign Bank Statement.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 3 per cent. During the week, the bank gained £31,500 bullion, and the proportion of its reserve to its liabilities was reduced from 43⅞ to 43 1/16 per cent, against 39½ per cent at this date last year. December 20th, the bank lost £25,000 bullion on balance. The weekly statement of the Bank of France shows a decrease of 725,000 francs gold and a gain of 1,500,000 francs silver.

At Government Contract Rates.—Treasurer Wyman is making arrangements to deliver fractional silver from Washington at the government contract rates with Adams Express Company, at the expense of the applicant. The government contract rates are considerably lower than could be obtained by private firms.

METALS.

NEW YORK, Friday Evening, Dec. 21.

Copper.—The market remains quiet, with Lake at 14⅛@15c., first hands asking 15½c., and other brands 14@14¾c., according to quality.

The most interesting feature from London is the fact that Best Selected is apparently following Chili Bars, the latter being considered the chiefly speculative article. The drop of Best Selected from £65 last week to £64 to-day indicates that the recent decline in Chili Bars, now £57, was not due to exclusively speculative influences.

Messrs. James & Shakspeare have issued the following statistics of copper, compiled from the Board of Trade returns:

	Jan. 1 to Nov. 30. 1883. Tons.	1882. Tons.
Imports:		
Pure in pyrites	13,902	14,381
precipitate	21,510	16,366
ore	14,706	14,356
regulus	8,399	8,274
Bars, cakes, etc.	32,571	32,091
	91,088	85,468
Exports:		
Raw (English)	15,491	11,579
Sheets	14,380	14,646
Yellow metal at 60 per cent	11,055	10,206
Brass at 70 per cent	3,103	3,201
	44,029	39,632
Foreign	10,208	11,830
	54,237	51,462

Lead.—Holders appear to be making an effort to stay the decline, some of them declining to sell Common at less than 3·70@3·75c. We have, however, been quoted Refined at 3·65c., which indicates that the attempt is not by any means general. The best season for Common has passed by, and buyers, having extremely bearish views in regard to the metal, will not touch it. In the present state of the market, quotations mean very little, as the market has not been fairly tested here for two weeks.

Messrs. John Wahl & Co., of St. Louis, wire us as follows to-day:

Our market is quiet. Sales will not aggregate more than 100 tons of Refined at 3·30c., delivered at St. Louis. Nothing is doing in Common.

Messrs. Everett & Post, of Chicago, telegraph:

There is a fairly active demand for both Hard and Soft lead, and prices are held stiff at 3·35c. However, scarcely any thing is offered at that. Some future lead has been sold here at 3·40@3·42½c.

Spelter.—This metal is, if any thing, exhibiting slight signs of weakness. We quote nominally 4@4¼c. London cables, £15 7s. 6d.

Antimony.—This metal is strong. There are no arrivals of Cookson's, though Hallett's is in fair supply.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Dec. 21.

American Pig.—Business is very quiet, though it is reported that more effort is making to close contracts for delivery next year at concessions fr om ruling rates. There is some uncertainty as to the immediate future, though furnace men are hopeful as to the prospects. Of course, a very dull week or two is now expected. We quote Foundry No. 1, $20@$22.50; No. 2, $18.50@$19.50; and Gray Forge, $17.50@$19, all at tide-water. Bessemer pig is dull, nominally at $20@$20.50. There was a sale of 2000 tons of Spiegeleisen, 20 per cent, at $28.75. We quote $29.

There have been no transactions at the Metal Exchange this week.

Scotch Pig.—Though the arrivals do not foot up to more than from 1000 to 1200 tons per week, some of the pig is sold from dock at a concession.

We quote ex ship and to arrive: Coltness, $22@$23; Langloan, $22.50@$23; Summerlee, $22.50; Eglinton, $20@$20.50; and Dalmellington, $20@$20.50.

At the Exchange, the following cable quotations were received to-day: Coltness, 55s.; Langloan, 53s. 6d.; Summerlee, 52s. 6d.; Gartsherrie, 51s. 3d.; Eglinton, at Ardrossan, 45s. 6d.; and Dalmellington, 47s. 6d. Warrants were 43s. 7d. to-day.

Steel Rails.—There has been considerable inquiry, and in the aggregate a large quantity of steel rails have been placed at $34 for winter delivery, and $35@$36 for summer work, all at mill. Much capital has been made out of a reported sale of 7500 tons at $30. These rails were heavy section seconds, and the price is in reality very good. Light seconds generally fetch from $4@$5 less than first-class rails, but are much more easily placed than heavy seconds.

Old Rails.—Quiet at $22@$22.50.

Philadelphia. December 21.

Pig-Iron.—In answer to inquiries as to the conditions of the pig-iron market, prominent makers and brokers assert that there is no weakness in standard brands. Large consumers who have been negotiating for the past week or so deny the correctness of this statement, and say that very favorable terms can be had, especially for large lots. So far as actual sales go to prove the condition of the market, they show that a few standard brands are held with considerable firmness, but that the great bulk of low-priced irons are moving at such prices as can be had. It is impossible to give exact prices, as every transaction fixes its own. It is stated that some large lots have been ordered for forward delivery, but the usual demand is for small lots for current requirements. Reports from furnaces show a slight increase in production and a more rapid diminution of stocks, showing an increase of stocks in consumers' hands. If some offers now in hand are accepted, a good deal of business will be done in January; but these prices will allow no profit to makers. On account of the fact that a good deal of mill capacity will take a long holiday rest, and because of the very low selling prices of finished iron, the movements in forge iron have assumed very small proportions, and prices are very low for all except the standard makes. For these, there is a good demand, and no concessions below $17 can be had. There are several buyers in the market to-day, looking after Southern irons.

Foreign Irons.—Consumers of Bessemer pig, in view of the condition of the steel rail market, are not anxious to crowd in stocks, but still some two or three brokers have instructions to buy at certain figures, $1 below asking prices. Within three or four days past, 7700 tons of ore have been received. Spiegeleisen is nominally $29.50.

Blooms.—Charcoal Blooms are selling at $55@$57, and anthracite at $47@$47.50.

Muck Bars.—Nominally $32.

Merchant Iron.—Nominally 2@2·10c., and common, 1·70@1·80c.; but when it comes to business, better terms can be had. Competition for business is depressing prices for refined iron in some cases down to 1·90c., and manufacturers say that they have no profit at that price. There was a good deal of inquiry in the market yesterday and to-day, and offers for small lots are in hand, and will probably be accepted. Country mills are shading prices, especially for common iron. There are rumors of large orders for cars to be given out in January.

Nails.—As indicated in former reports, a downward tendency is at work in nail prices, and quotations are now given at $2.45@$2.55. The jobbing demand is light. Eastern nail men are in better spirits since the announcement of the suspension of six weeks to take place in Western mills. It is thought that this will check the downward tendency of prices. The favorable weather has permitted a large amount of building to be continued, and the consumption of nails up to this time has been quite liberal.

Plate and Tank Iron.—Quotations show a slight decline, and demand is light.

Structural Iron.—The movements in structural iron are of a very trifling character, and nothing of importance will be done until January.

Steel Rails.—Quotations are nominally $34@$35,

and there is considerable anxiety among makers to secure orders for January and February.

Old Rails.—Spot lots sold at $23.50. Southern rails are looked after, and small lots are bought.

Scrap-Iron.—Good scrap has dropped 50c.@$1 per ton. Cargo, $22 nominally.

Pittsburg. December 20.

The workmen at the Edgar Thomson mill have accepted the reduction of 13 per cent in their wages, and all goes on quietly. The workmen in the North Chicago Rolling-Mill have accepted a reduction of 10 per cent. The strike on the Monongahela River leaves some 2000 men idle. The iron trade shows little difference compared with what it has been reported to be for the last week or two. Consumers of pig-iron are purchasing from hand to mouth, and some orders are withheld on account of a difference of 25c. per ton. Forge iron, Lake ore, is held for $18, and there is considerable firmness shown by local makers because of the depletion of stocks said to be going on, but which consumers are loth to believe in. The Lucy furnaces are both out, and two or three more, it is said, will soon follow. The talk is, that stocks are light; but buyers have very little trouble in getting concessions on outside inferior iron, though iron made in the country is held with more firmness. Lowest sales of Gray Forge have been made at $16.50, and numerous sales have been made all the way from that figure up to $17.50. Muck Bars are dull at $32. Very little Merchant iron is selling, and quotations are 1·60@1.80c. Consumers generally are running with small stocks, and this is considered the most favorable feature of the market. If any large proportion of the consumers who need stocks come into the market in January, the demand will be heavy, and prices will certainly improve. Car-load lots of nails are selling at $2.35@$2.50, and offers are in hand at $2.25@$2.35. Discounts on Pipes are 70@75 per cent; Tubes, 60@62½. There is an active inquiry for old rails, but few sales are reported. Large lots are wanted for delivery in April, but sellers decline to accept the offers which are made. Steel Rails are quoted firm at $35. Inquiries are numerous, and offers are in hand something less. Low-grade steel is dull.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Dec. 21.

Anthracite.

For the present, the danger of a rupture of the "harmonious" relations between the anthracite coal companies seems to have passed by. At one time, it seemed imminent. For some sizes, for instance, chestnut, there is more inquiry, but the stock afloat and in cars is large, and there is no scarcity. So far as the trade in general is concerned, it is still dull and quiet; but in spite of the urgency of early action, no decision as to what is to be done in January has been reached. Experience has apparently taught the companies that if they want to reach any conclusions at all, it is well to start early in discussion. Prices are practically unchanged, being $3.50 for broken and $3.95@$4 for stove, f. o. b.

The anthracite coal tonnage of all the carrying companies for the eleven months of 1883, ended November 30th, was 29,659,886 tons, an increase of 3,139,229 tons, as compared with the same period last year. The stock of coal on hand at tide-water shipping points, November 30th, was 696,380 tons.

Bituminous.

From the Cumberland region, it is reported that tomorrow the water will be drawn off from the canal. Trade is, if any thing, flatter than it has been, and prices are naturally in buyers' favor.

Pittsburg.

The railroad trade a week ago seemed in the worst shape; but within the past few days, events on the river go to show that the coming winter will be marked by such dullness in that branch of the industry as has not existed for years. The policy, on the part of most operators, of availing themselves of every rise to send out thousands of tons of coal, irrespective of the condition of stocks and of markets below, is now producing its legitimate results. Unusually large quantities of coal in every port and a restricted demand have decided operators to close most of the largest of the seventy pits along the Monongahela and Youghiogheny rivers. Walton & Co. shut down on Saturday the last of their three pits, reducing 800 men to idleness. W. H. Brown's Sons will close all their works save the one at Saltsburg, and will discharge at least 600 men. John A. Wood, O'Neil & Co., and other large firms, had not decided on Saturday what to do, but would at all events run very slack, and devote their energies to getting matters in shape for a "freeze-up." This condition of the trade is, of course, intensified by the extreme dullness in the iron and steel trade and the glass trade at this recognized center of those great industries. Prices for river coal are nominally 7½c. for second pool at Louisville; 7¼c. at Cincinnati, with no prospects of better prices unless a long severe cold period should occur. Fourth pool coal can be purchased at 6½@6¾ to 7c. at these points. This matter of coal from the different pools is just now a live topic for the trade. The testimony given before the arbitrators last week included some spicy accusations on the part of the miners' representatives, and by one or two lower pool operators also. They charged well-known operators with filling all orders with fourth pool coal, which coal, by the time it had passed Cincinnati, became, in some mysterious way, the best "second pool coal." Fourth pool coal is inferior in quality, being "leaner" in heating and gas-making qualities. It costs a half-cent less to mine, and the gentlemen before the arbitrating committee took advantage of the occasion to say some pretty rough things about men who would cheat their customers down the river and get rich at the expense of the miners too. Considerable feeling has been stirred up in this direction, and Umpire Weeks has had a trying time of it, as he was present at all the conferences. Friday last, all the testimony was in, and in a few days Mr. Weeks will decide how rates shall rule in the fourth pool.

Coke is going the way I felt certain it would. Prices being on bed-rock (95c.@$1), they could not go lower. So production is to be restricted, the coke-makers enjoying two days of rest per week, Sunday and Wednesday. All ovens charged Friday are drawn Monday, those charged on Saturday are drawn on Tuesday, and no charging or other direct work is done on Wednesday. Thursday charges are drawn on Saturday. This reduces the full and usual output by 15 per cent, say to 3600 cars per week. Mr. H. C. Frick could not speak of the outlook. It depended upon the future of the iron trade. The valleys of Ohio take now barely half their usual amount, and the stoppage of one furnace at the Edgar Thomson works, and the two Lucy furnaces here, represents a falling off of 50 cars per day in the demand. I might add, for the benefit of the readers of COAL, that the extensive coke firm of H. C. Frick & Co. has opened a branch office in Philadelphia, at No. 313 Walnut street. Prices of crushed coke remain at $1.75 per ton, about as low in proportion as the uncrushed article.

Chicago.

Nothing is heard any more of a scarcity of cars, and when one considers the often-repeated cry of a few weeks since, "Cars are so scarce we can get no coal forward," the question naturally comes up, How came the situation to change so quickly? A cautious and well-informed coal man suggested to your correspondent that the shortage in the supply of cars during October and November was not an actual but an enforced shortage. Eastern operators were obtaining such rates to Buffalo that, with the low lake freights holding most of the time, it did not pay them to ship by rail through to the West, and the shortage in the car supply was created to further the ends of these shippers. The suggestion did not appear far-fetched, but, in the light of recent events, quite plausible.

The chief interest in the bituminous market the past week has centered in the fight between shippers of Hocking Valley coal. As near as can be learned, the story is about this: Four or five shippers, representing the chief interests in Hocking Valley coal, attempted to freeze out an outside shipper who had arrangements with a railroad line into Chicago over which the other shippers did not forward their coal, and which line had been left out of consideration by them. The shipper, placed on the defensive, met the cut of the others in Hocking Valley from $3.75 to $3.25—which cut was made at the opening of the week—by a still further cut to $3.15, and, as he seemed able to carry the war on to an uncomfortable extent, the other shippers came down a little, and to-day the price for Hocking Valley is $3.35. As a consequence of the fight, large shipments of Hocking Valley have been made. The general market for soft coals is quiet, under a somewhat lighter inquiry and a larger supply. The mines in the Indiana Block District are not running up to their full capacity.

Horsford's Acid Phosphate.

Marked Benefit in Indigestion.

DR. A. L. HALL, Fair Haven, N. Y., says: "Have prescribed it with marked benefit in indigestion and urinary troubles."

WANTED.—POSITION AS RESPONSIBLE business agent or manager of mines or metallurgical works, by a gentleman of long experience in similar positions in Nevada and Colorado. Address
MANAGER,
P.O. Box 203, N. Y. City.

TO INVESTORS.

The Keith Electric Company, having secured and paid for valuable patents covering a complete system of electric lighting, and having demonstrated the economy and reliability of their light, are now prepared to push its introduction with the utmost energy. For this purpose a limited amount of the stock is offered at $20 per share.
For full particulars address
AUSTIN GALLAGHER,
Drexel Building,
Corner Wall and Broad Streets, New York.

DIVIDENDS.

SAN FRANCISCO, Dec. 14, 1883.

THE FATHER DE SMET CONSOLIDATED GOLD MINING COMPANY has declared dividend No. 30, of TWENTY CENTS per share, payable at the office of Laidlaw & Co., 14 Wall Street, New York, 31st inst.
Transfer-books will close 22d inst.
H. DEAS, Secretary.

ONTARIO SILVER MINING COMPANY,
15 Broad Street,
NEW YORK, Dec. 19, 1883.
DIVIDEND NO. 90.
The regular monthly dividend of FIFTY CENTS per share has been declared for November, payable at the office of the transfer-agents, Lounsbery & Haggin, Mills Building, 15 Broad Street, on the 31st inst.
Transfer-books close on the 24th inst.
LOUNSBERY & HAGGIN, Transfer-Agents.

NEW YORK, Dec. 15, 1883.

THE CONTENTION CONSOLIDATED MINING COMPANY has this day declared an extra dividend of TWENTY-FIVE CENTS per share, payable December 24th, instant, at the office of the Farmers' Loan and Trust Company, 20 and 22 William Street, on all stock registered in New York.
Transfer-books close this December 15th, 1883.
W. HART SMITH, Vice-President.

ROTHWELL'S

Great Map of the Wyoming Valley.

This, the most elaborate and accurate topographical map ever made in this country, outside of the Coast Survey, covers an area of TWO HUNDRED SQUARE MILES, and the work upon it cost over $12,000. It represents a coal-field which produced in 1882 over 13,000,000 tons of Anthracite. The Map was constructed altogether from original surveys. Every Road, Colliery, Building, or land or property line existing at the time is accurately located. The surface configuration is shown by CONTOUR LINES TEN FEET APART, VERTICALLY; and the elevation of every point above sea-level is given

But a small edition of this Map was printed, and the plates were then destroyed.

A few copies are for sale.

Price: On thick heavy paper $25
On bond paper, for mounting 25

The six sheets can be mounted separately, or in a single roll 15 feet long by 42 inches wide.

DR. THOMAS M. DROWN has resigned the secretaryship of the American Institute of Mining Engineers. Among other candidates, we learn that Dr. R. W. RAYMOND and Mr. CHARLES KIRCHHOFF, Jr., have been nominated for the position.

A MEETING was held on the 27th of December, at the Fifth Avenue Hotel in this city, to arrange preliminaries for bringing about an agreement by which coal and iron ore will be allowed to enter free of duty into Canada and the United States. Those interested in mining coal in certain bituminous districts of Pennsylvania and Ohio, and those engaged in mining iron ore in Canada and in manufacturing pig-iron in this country, are in favor of such reciprocity.

AFTER a good deal of dickering, the railroad companies tapping the Connellsville region have come to an understanding, although it is rumored that the Pennsylvania Railroad is not quite content with its share. The allotment of the new coke pool, to take effect on the 1st of January, is given as follows: The Pennsylvania Railroad, 55 per cent; the Baltimore & Ohio Railroad, 25 per cent; and the Pittsburg & Lake Erie, with its new extension, the Pittsburg, McKeesport & Youghiogheny, 20 per cent. This has the appearance of an armistice, during which the contestants will probably continue to maneuver for position favorable in a future fight.

IN our next issue, the ENGINEERING AND MINING JOURNAL will come to its readers enlarged and with new claims to support through the advantages offered by the consolidation with *Coal*, a journal which was established and has been conducted in the interest of the Coal Trade—the producers, vendors, and consumers of coal. As an independent and accurate exponent of this industry, it has met with a most gratifying and, we believe, exceptional success. This encouragement and appreciation, and the calls upon it to extend the sphere of its usefulness by bringing in such collateral and allied industries as the iron trade and other large consumers of coal, have convinced the publishers of *Coal* of the advantages that would accrue to its patrons by giving them that full information concerning those metallurgical industries which are among the largest consumers of coal, and which information they have now to glean from the columns of other periodicals. With the view, therefore, of greatly increasing the field of information especially valuable to the members of the coal trade, and of benefiting the advertising patrons of *Coal* by bringing their wares to the notice of a much larger circle of purchasers than is possible through a journal devoted exclusively to any one department of the coal-consuming industry, it has been decided to merge *Coal* in the columns of the ENGINEERING AND MINING JOURNAL.

The patrons of the latter will also be great gainers by the step taken. They will be able to avail themselves of the facilities for the gathering of news which *Coal* has acquired during two years of close attention to the interests of an industry upon which all are to some extent dependent. Special correspondents of acknowledged ability will weekly report on the fluctuations in the markets at Boston, Buffalo, Pittsburg, and Chicago, discussing the many questions which affect the prosperity of the coal trade. The columns of the ENGINEERING AND MINING JOURNAL AND COAL will closely reflect progress in all branches of coal mining, the utilization of fuel, and the local development of our vast resources.

DURING the past year, we have followed closely and with much interest the work of M. P. MANHÈS, at Septèmes, France, in developing the method of Bessemerizing copper mattes, because we believe that the many modifications in practical details which he has worked out are likely to make the process one of the greatest importance to the copper industry of this country. A few years ago, it might have been capable of a few local applications. To-day and in the near future, it will be an important aid in working material which constitutes the source of fully one quarter of our total product, which has risen to quite 45,000 net tons of metal. We trust that it will not be long before this latest and most important step in the simplification of copper smelting will have found a home in this country.

We are pleased to notice that M. MANHÈS has invaded another branch of metallurgy, in which, it is true, comparatively few are interested in this country. M. MANHÈS has recently begun a series of experiments on a small scale in concentrating nickel mattes from the Berg Seljen mines in Norway. The *Génie Civil* tells us that Mr. J. GARNIER, so prominently identified with the development of the famous mines of New Caledonia, and M. G. SALOMON brought a lot of 16 per cent nickel matte from Berg Seljen. Three lots of 50 pounds, melted in a crucible, were run into a converter of the same type as that used for Bessemerizing copper matte, the pressure of the blast being from 350 to 500 millimeters of mercury. The blowing was stopped respectively in five, ten, and fifteen minutes with the following results:

	Copper.	Nickel.	Iron.
First blow:			
Before blowing	5·86	16·30	22·40
After 5 minutes	11·00	30·73	n. d.
Cinder	0·05	1·51	n. d.
Second blow:			
Before blowing	5·86	16·94	22·40
After 10 minutes	14·13	50·80	10·00
Cinder	0·60	3·00	n. d.
Third blow:			
Before blowing	5·80	16·60	22·40
After 15 minutes	11·30	70·06	1·20
Cinder	0·30	4·00	n. d.

So far as they go, the results are decidedly encouraging. They clearly indicate that it is not a very difficult matter to concentrate low-grade nickel mattes into a product of such high tenor in nickel that they can go directly to the refining processes. On one vital point, however, the experiments furnish no data. The material worked with is called a "matte," and from its origin we judge that it carries little arsenic. It remains to be seen in what manner arsenic behaves in the converter. If it obstinately clings to the metal, the advantages of a rapid and cheap concentration would probably be outbalanced by the drawbacks incident to the presence of arsenic in great quantity in later operations. It is true that, so far as its relations to copper are concerned, M. MANHÈS has assured the metallurgical world that arsenic is not troublesome. He has not, however, submitted figures to substantiate his claim. One point speaks in favor of the probable elimination of at least a considerable proportion of the arsenic. It is known that a large part of the sulphur, when Bessemerizing copper mattes, is volatilized, escaping as sulphur, not as sulphurous acid, as might be inferred from the fact that the process involves almost a violent oxidation.

With all the reserve due to the lack of data on the point referred to, there is some satisfaction in the thought that a promise is held out of the cheapening of so useful a metal as nickel. Especially so, as it is, we understand, one of the component parts of the alloy which is brought out in Pittsburg by a leading firm of iron-makers as a protective coating for iron and steel.

THE MINES OF FRESNILLO.—II.*

Special Correspondence of the Engineering and Mining Journal.

Of even more general interest than the data as to the Proaño mines, which this Fresnillo memoir provides, are the metallurgical notices and the statistics of work done in the great Hacienda Nueva, the typical establishment for the treatment of silver ores by the patio.

It seems that long ago the surface chlorides were amalgamated in copper vessels by a method known as *beneficio de caza*. On the resumption of work in 1830, the base metal ores were smelted; a small quantity of chloride was still subjected to the *beneficio de caza;* but 95 per cent was treated by the patio at three small establishments near Fresnillo and at others near Zacatecas. But no statistics of cost are preserved. Between 1831 and 1844, however, was erected the great Hacienda Nueva at a cost of $340,132. It was during this period that Duport wrote his work on the production of the precious metals in Mexico, which gives plans of the new Fresnillo works and a full description of the treatment. In Duport's day, however, the stamps and arrastras were worked by mule power. Subsequently the 60-inch cylinder engines, when replaced at the mine by the 80-inch, were transferred to the hacienda.

This large establishment, whose patio can hold 64 *tortas* of 120,000 pounds of ore each, or 3840 tons, is the largest of its kind in the world. Yet of average mixture of oxidised and rebellious ores it could treat only 900 tons weekly. Herein lies the disadvantage of the method. The first cost is vastly greater than that of a mill on the Washoe process, and the ground occupied incomparably more. The establishment does not treat more than would a 50-stamp silver mill, and yet it covers an area of 900 feet by 900 feet. The plant consists of two 60-inch cylinder engines, 314 arrastras, 12 stamp mills, pump-washers and sluices, magistral furnaces, and stables for 1500 animals—all surrounding the court or *patio*, in which, as above stated, 64 *tortas*, about 15 yards in diameter each, can be treated at the same time.

The theory of the patio has always been a vexed question. It depends, of course, on the action of the chlorides of copper, whatever that action may be, on certain silver compounds, fitting them for the attack of mercury. The same reactions are taken advantage of when salt and bluestone are added to the pans in the Washoe process, and the Kröhnke method, used so successfully in Chili, is based upon them. The advantages of the patio are that, the grinding once effected, no mechanical power is consumed, and that no furnace treatment, and therefore no fuel, is required. The disadvantages are the length of time consumed in the operation and the great expenditure of animal force. In the small way, a patio plant can be extemporized at little outlay; and where fuel is scarce and animals plenty, and the climate sufficiently temperate, probably no method can compete with it. The results are as close as or closer than are obtained on similar ore by our hasty methods of amalgamation. The question, therefore, presents itself, whether, by employing good machinery and kneading the patio by some mechanical appliance instead of the feet of animals, a perfect extraction could not be effected, time saved, and expenses, in some cases, lessened.

The operations are:

I. The coarse crushing, which is at Fresnillo, as elsewhere, effected by stamp-mills even more primitive than those still to be seen in Cornwall and Germany, with wooden stems and clumsy iron shoes.

II. The pulverization. The coarse sand from the battery is reduced to pulp in the arrastra, a basin whose bottom and rim are constructed of large stones, in which another large stone is dragged around by mule-power. The product of an arrastra is from 600 to 1500 pounds per day, according to hardness of material and fineness of grinding. At Fresnillo, very fine grinding is not preferred, and the yield at each arrastra is about half a ton. As great a disparity as exists between a Mexican and a Californian stamp battery divides the Mexican arrastra from the grinding-mill used at Escobar and Orsa's great silver establishments in Chili. The pulverization is effected by the same mechanical elements, applied in the same way; but the whole structure is of iron, the parts are perfectly adjusted, the feed and discharge are automatic, and the pulp remarkably fine and even.

III. The pulp as received from the arrastra is partially drained in slime-pits.

IV. But it is still semi-fluid when thrown on the floor of the patio in quantities at Fresnillo of 60 tons, and is prevented from spreading by a temporary barrier of timbers and manure. Thus it is left until evaporation has reduced it to such consistency that it can be still easily penetrated by the feet of the animals.

V. The metallurgical treatment consists:

(*a.*) Of the addition of salt, 2½ per cent by weight of the *torta*, after which the mass is turned over by shovels and trodden by from eight to fifteen horses or mules. These are tied to and revolve around a stake which forms the center of the *torta*.

(*b.*) Sometimes with the salt—more generally twenty-four hours afterward—from 1 to 2 per cent of *magistral*—roasted cupriferous pyrites—is incorporated with the mass. In certain localities, bluestone in proportionate quantities replaces the roasted ore.

(*c.*) The gradual addition of the mercury now begins, and the skill of the *azogueros* (mercury man) is called into play. He watches the progress of the amalgamation, adding magistral when it lags, and mercury when the consistency of the amalgam indicates; and he kneads the pulp with the troop of horses oftener or less frequently as his judgment dictates. During the winter months, especially at Fresnillo, when the surface of the *tortas* freezes at night, peculiar complications supervene, which tax his skill. Duport well describes the indications which guide the *azogueros* when he says: "Without pretending to isolate the examination of the different parts of the *tentadura* tests, one may say that the color of the mercury is the guide for the proportion of the *magistral*, the condition of the *limadura* (the flowering and granulated mercury) indicates the daily progress, and the greater or less degree of solidity in the amalgam determines the addition of more mercury and the end of the operation."

VI. The amalgamation completed, the ore passes to the washers, and the amalgam is retorted.

The time occupied varies from fifteen days in summer on free ores to thirty or forty days when the season is cold or the ores base; but the note to page 35 gives the result of Henry MacIntosh's investigation at the Hacienda del Salto on the accelerating effect of continued motion: "Two *tortas* of the same weight and the same mixture of ore were spread at the same time upon the *patio*. One of them worked with eight *repasos* of five or six hours each, at intervals of three or four days, required twenty-seven days. The other one, worked by causing the same number of mules employed in the *repasos* of the first one to travel over it uninterruptedly day and night, was finished in eighty hours. The yield of silver and the loss of mercury in the two cases were sensibly the same. But the cost of the *repasos* being very high at Guadalupe y Calvo, a double quantity of work for the mules in order to gain time was not profitable."

When watching the animals plodding through the pulp, it must occur to every one that, where steam-power is as cheap as animal power, or where water-power is available, the work would be better done by a machine like a great chocolate-mill, whose rollers would be provided with large teeth.

Such in outline is the patio process. The first statistical exhibits from 1835 to 1844 are given in general terms only. In that period, $8,261,875 worth of reagents were employed, in the reduction of which, quicksilver at the average cost of $1.33 per pound was used, and cost $2,128,000; magistral cost, $292 500; salt, $841,375; total, $3,261,875. The average loss and consumption of mercury declined to 10½ ounces per mark of silver, and the cost of production fell toward the end of that period to $9.75 per ton, exclusive of mercury.

The results, materials consumed, and cost of beneficiation at Proaño for the next period, namely, from 1853 to 1862, as tabulated in the memoir, are exact and worthy of study.

The totals are as follows:

Ore worked, tons	452,284·80
Silver produced, marks	1,096,281·32
Value of silver	$9,825,598.68
Salt consumed, cargas	186,229

Or 123 pounds per ton = 6 per cent.

Magistral consumed	7,922 tons, or 35 pounds per ton = 1·75 per cent.
Quicksilver "	904,306 pounds,
	or 1·9 pounds per ton of ore treated,
	or 13·197 ounces per mark,
	or 0·87 ounce per $1 worth of silver recovered.
Average yield	2,424 marks,
	or $21.74 per ton.

	Per cent.
Average difference between yield and assay value	19·480
Highest difference	24·000
Lowest "	10·435
Cost of treatment	$5,051,769.66
	or $11.169 per ton.

During that period, the deepest ores were treated—ores so base that they would have yielded so imperfectly to pan amalgamation that our mill men would have subjected them to a preparatory chloridizing roast. They consequently consumed more chemicals and more labor in their treatment than if they had been oxidized by nature; for, whether decomposition of a base ore takes place rapidly in the furnace or slowly in the *patio*, reagents to effect the decomposition must be consumed, and labor to bring these reagents into contact with the ore and with one another must be expended.

Considering that the cost of the articles consumed, taken from a price-list of supplies in 1844, was as follows: Salt, $10 per ton; magistral, $50 per ton; quicksilver, $1.20 per pound; wood, $22.50 per ton; and that all kinds of iron-ware and supplies were inordinately dear, it must be admitted that the patio process is not an uneconomical method, when it can treat a base ore under these conditions for $11.16 per ton, and not an insufficient one when it extracts 80 per cent of its silver value from such refractory material. It would surely be worth while for our metallurgists in Mexico to consider whether the method can not be so modified that its defects will be remedied, while its advantages are retained.

J. D., JR.

* *Sketch of the Great Historic Mines of the Cerro de Proaño, at Fresnillo, State of Zacatecas, Mexico.* 1883.

POSSIBLE ECONOMIES IN MINING IN THE SAN JUAN COUNTRY.

Special Correspondence of the Engineering and Mining Journal.

Early in April of this year, your correspondent, with two other large ore-buyers, made an estimate of the probable output of the ores of the precious metals from Silverton during 1883. With a thorough knowledge of the working mines and their dumps, it was not difficult to arrive at a fair basis of computation, and all three agreed very closely in the aggregate amount, the average of the several estimates being, in round numbers, 18,500 tons. The actual shipments for the year (allowing for the whole month the daily average since the 1st of December to date) amount to about 16,000 tons. Had the price of lead and the demand for copper ores continued as in the month of August, there is no doubt that the output from the mines would have been increased by at least 2000 tons. When it is considered that many of the mines included in our estimates have produced less than might reasonably have been expected, while the deficit from this cause has been largely made up from new sources of supply, it may safely be stated that the productive capacity of the district, without further development, is not far from 25,000 tons per annum. But this estimate means much more than at first sight appears. There has been no time this season when ores carrying less than from 20 to 25 ounces of silver or its equivalent in value, per ton, could have been shipped without loss, and when the cost of mining and hauling to the railroad is added, we may regard ores worth $30 per ton as practically unremunerative, on the average. It is evident, therefore, that we shall not go wide of the mark if we add at least thirty per cent for such ores as have been produced by mines unable to ship the whole of their output, and an intimate knowledge of the dump ore of the region convinces me that this allowance is none too large for fairness. This gives a feasible product of 32,500 tons, to which must be added a considerable amount to cover the neatly arranged dumps, which have been carefully held back by miners upon the mistaken notion that these

Digitized by Google

will influence the sale of their properties more than authentic certificates of mill-runs. I believe I shall be considered conservative by the best judges, if I allow 1500 tons for this item, making a total possible contribution of 34,000 tons, or a daily average of nearly 100 tons.

There is abundant reason for placing the average value of the ore shipped this year much higher than last year's product. The accepted estimates for 1882 ($650,000), were based upon an average of $75 per ton. We may take $85 as a fair average for 1883, thus reaching a grand total of $1,360,000. My own figures early in the season were $1,500,000, which amount would no doubt have been realized had not the shipments fallen off materially, owing to the drop in the market price of lead in October and November. The actual product, allowing for ores not shipped, has not gone short of $2,000,000, exclusive of large quantities of concentrating grades, which may eventually be worked at a profit. Still further allowances must also be made for vast stores of rebellious ores, for which there is no market immediately available, but which really present no metallurgical difficulties that have not elsewhere been overcome, and which will, ere long, be treated successfully in Colorado.

A careful study of the resources of our district, extending over a period of nearly five years, and a most intimate acquaintance with the character of our ores, gained by extensive handling of them in sampling and concentrating mills, together with frequent analyses, qualitative and quantitative, in the wet way and by means of the blow-pipe, have given the writer a tolerably clear insight into the capabilities of the country and the essential features of its future prosperity. In every mining enterprise, there are four items of expenditure which practically control the profits to be realized, and each of these is affected by a variety of circumstances, making it necessary to take advantage of every possible economy in practice in order to achieve success.

The first consideration is the cost of mining. This is dependent upon two things, namely: A. Labor. B. Character of rock to be worked. In all new countries, skilled miners are lacking, and such labor as can be secured must be hired at very high rates. To render this efficient and economical, it is essential to employ well-trained foremen of shifts, who will direct the work in detail, and these must be responsible to a competent superintendent capable of planning the general workings and properly developing the mine. Even with skilled labor, this organization is proper, but with the crude material frequently employed in the West, it is impossible to succeed in any other way. Labor is too high-priced now for what it can ordinarily accomplish, and we must look for economy of mining partly in the direction of careful selection, or in the policy of grading compensation according to quality of work. By some such means it will eventually be possible to reduce the cost of mining a ton of ore several dollars below the present average. Contract labor has one advantage now, that inexperienced managers or slow-working companies can avoid considerable risk; but competent managers usually find it very difficult to let contracts at fair prices, and the cost of incompetence is ruinous. We can not hope to bring down the average cost of mining by any just gradation of labor, so long as the untrained mine managers are largely in the majority.

The character of the rock varies greatly in this region; but there are comparatively few mines in which the average per thousand feet is much different from the general average of the veins of the district. Hence, we have a right to expect that some basis for calculation may be found in the actual prices paid for contract work throughout the county. But here, again, we are at sea. I could cite numerous instances where good managers have run drifts in tough rock by day labor at a cost less than half the price paid by others for contract work in the most favorable ground. If we class development-work as permanent improvement, and take cognizance only of the ore extraction *per se*, we may get a more reliable estimate, but, again, I have in mind not a few actual cases where one manager has made the same work cost just one half what another has expended per fathom of stoping ground. It is, then, quite apparent that whatever saving we may expect from the application of labor or the choice of favorable vein material must come almost wholly through the substitution of experienced and thoroughly competent managers for many of the amateur low-priced overseers now employed. It is impossible to state what is the present average cost of mining per ton of ore, but it is safe to say that it is nearer ten dollars than five dollars. I know of two mines worked upon the same vein under quite similar conditions. One is in charge of a competent superintendent, the other is managed (?) by a speculator totally ignorant of the first principles of mining. The latter has taken out ore at a cost of eight dollars per ton, and the mine is left in an unworkable condition, and undeveloped; the former has developed his property with far less expense, and has taken out much more ore from inferior ground, at a cost of $2.75 per ton, keeping the mine in good condition, and he is still taking out ore.

The second source of outlay is the transfer of ore from mine to mill or railroad. Almost without exception, the pack train and the wagon are relied upon for this purpose. No united effort has yet been made to secure cheaper methods, or to lessen the present cost of packing and hauling. The average rate the past season has been $1 per ton for packing and 50 cents per ton for hauling, for each mile of travel, though occasional lots have been moved more cheaply. I can not now recall one instance of transportation by teams belonging to the mining companies, and but two or three pack-trains have been worked in this way for short distances only. Teamsters do not often amass wealth rapidly from this business, but no doubt they, or the mine-owners themselves, could transport the ore much more cheaply, if a regular and continuous supply could be confidently relied upon. Packers can not do as well as the teamsters usually, but they have no expenses of moment when idle. The remedy for the high cost of shipping by trail will be the construction of tramways; but few properties are yet sufficiently developed to warrant the necessary expenditure. However, several prominent mines are shipping large amounts of ore by burros and wagons, which could annually save thousands of dollars by the use of some economical wire-rope or surface-rail system of transfer. It would require too much space to detail here the facts and figures upon which I base my statement; but I am convinced by long and careful investigation that a reduction of cost can be made of at least 20 cents per ton per mile, upon the average, by proper management. This would be equivalent to an average increase of fully $1.50 per ton in the net receipts from ore shipped.

The third item of expense is railroad transportation. The low price of lead has already had a most serious effect upon our local mining industry, and worse results must follow in the spring, unless some radical revision of the railroad tariff is brought about this winter. Much is anticipated from the Miners and Smelters' Association of Denver, especially as several prominent railroad officers are enrolled as members of that body. Mr. A. S. Hughes, the General Freight Agent of the Denver & Rio Grande Railroad, has always shown a commendable desire to adjust rates upon an equitable basis, but his decisions sometimes appear to be based upon wrong premises and insufficient knowledge of the facts.

In 1882, after the completion of the railroad to Silverton, the ore-shipments averaged less than 20 tons per day, with the freight to Denver and Pueblo at $16 per ton. For the ten months during which the rate was $12, and the price of lead unchanged, there were shipped, on an average, at least 40 tons daily; and with the freight reduced to $8, my calculations show a probable business of 80 tons per day for the railroad, which, I am sure, could easily be increased next season to 100 tons or more with a $6 tariff. The exact cost of transportation is not now within my reach, but all the commonly accepted principles of railroad traffic are wide of the truth if it will not pay better to haul 80 tons at $8 than to transport 40 tons at $12, with the same motor and train-gang. The railroad's policy heretofore has apparently been to get all the country would or could stand; now the time has come when the officers ought to see that we can not stand the present tariff. Four dollars per ton less for freight charges in September would have signified so much more profit to the miner; now it merely enables him to ship ores which can not be handled with a rate of $12. Even at $6 per ton, many good mines would realize less for their output than they were getting in August, with freight at $12. Hence any reduction in the tariff that the railroad can possibly afford will not throw greater profit into the miner's hand, until there comes a reaction in the lead market. Without a liberal reduction, the railroad will suffer very serious losses in traffic. Already with all the roads in excellent order, and many mines putting out ore in abundance, the weekly shipments have fallen off from 600 tons to 180 tons.

The fourth and last expense directly affecting the ore-seller is the charge for treatment at the reduction-works. The recent organization of the Miners and Smelters' Association at Denver is as opportune as it is welcome to those who have at heart the true interests of mining. In the first place, it may do more than any other agency toward dispelling the woful ignorance which exists concerning the processes of ore treatment, and it may possibly aid in convincing many that successful mining requires as much skill and training as the profitable reduction of ores by smelting or other methods. It is a common claim of the Western press that the smelters have been making undue profits, and that their treatment charges have been excessive. While it is proper to reply that the mere statement of such a claim by a novice in the art and science of metallurgy, is insufficient proof of its truth, it may be worth while to discuss the question briefly. The nominal charges for smelting galena ores have ranged from ten to twenty dollars per ton this season. Ore buyers have, however, been instructed to purchase very choice grades, in some cases, on the basis of eight, or even seven dollars off for treatment. Of course, it will be understood that the lowest charges have been for ores of very clean character, running unusually high in lead; but the highest deductions, it should be remarked, have only occurred in very lean ores, often of a rebellious nature; and besides, the lead has been estimated at very good prices, before the smelting charges have been levied. This year, most buyers have also paid something for each unit of lead in any ore, regardless of the amount, but last year nothing was allowed for this metal in ores carrying less than 20 per cent. Again, silver and gold have usually brought higher percentages of market value than formerly. These facts all go to prove that the reduction-works have done more in the way of concession than any other agent coming between mine and bullion.

We can now more intelligently discuss the question of the possible economies to be introduced into the mining business in the face of the present conditions. One plan, which has been advocated to some extent, is to reduce miners' wages from 50 cents to $1 per day. This has been tried in an adjoining county, and has produced there a state of war. I can not sympathize with any set of men who attempt to accomplish their ends by force applied to those who are willing to accept the terms of employers. At the same time, it seems very evident that the reduction of wages should be adopted as the last resort in times of depression. If the mines can not be run at a profit without cutting down the cost of labor, and if this action will make them pay their way, it is certainly better for all concerned to apply the remedy, and the workmen are unjust to themselves if they do not make the best of it and acquiesce at once. However, the item of labor is not the most onerous burden by any means, and the intelligent manager will exhaust every effort to secure economy in other directions before he will reduce his pay-roll. A far better plan will be to replace incompetent men by skilled miners. The wages now paid are not excessive so much from the amount expended as from the inferior work often performed. If it be impossible, as it seems to be now, to bring about a proper gradation of wages, according to quality of work, it behoves the wise manager to employ only the best labor obtainable. If $4 or $3.50 per day is too much for the average labor performed, let those who are not average workmen stand aside, and put in their places the best men that can be found. This will encourage the worthy, and stimulate or weed out the incapable. While upon this topic, let me throw out a hint to the trustees of large mining corporations. If my views are correct, it will avail little to adopt them unless the same principle be applied to the managers and superintendents and foremen themselves. More money has been wasted in this country at the hands of incompetent overseers of all grades than has ever been expended for labor, including the poorest.

As for the feasibility of reducing the cost of mining in other ways, there is no doubt of the propriety of employing power drills and other machinery, when handled by competent men. Not only will the use of these machines lessen the cost per foot or fathom of excavation in drifts, shafts, and stopes, but the cost per ton of ore extracted will be much reduced by the increased output, which bears its share of the general expense, with-

Digitized by Google

out additional outlay for such items as management, interest, taxes, and permanent improvements.

The rate for transportation to mill or railroad may be reduced in two ways, and I do not apprehend that those who live by this business will lose any thing of consequence by the change. The imperative need is the construction of tramways to carry the ore to points more accessible by trails or wagon-roads. By the use of such means, it is safe to predict a saving of one dollar per ton in very many instances; and if the same system be extended, so as to provide mechanical modes of transport along our gulches and cañons down to the railroad, it will be possible to effect a further reduction of at least three dollars per ton upon the whole product of the district.

Another step toward economy, which may be immediately taken, and without the objection of large original cost, is the employment of teams owned by the companies themselves. Probably the saving by this method would amount, in many cases, to several dollars per ton.

Whatever reduction can be secured in railroad rates will, however, prove most beneficial. We now pay $12 on every ton of ore shipped to Denver or Pueblo. If we could save $4 per ton, we should draw this much more cash from outside, and put it into circulation here. None of the money paid for freight is employed in business here, and nearly all of it is received by the railroad company at the point of destination. In more ways than one, a reduction of these charges would benefit us and increase the net revenue of the railroad. Let the rate be put at $8, and the increased output arising simply from the ability to ship ores of lower grade (vast quantities of which have already been mined) would throw into the miners' hands fully $100,000 more next year than can be expected with the present tariff. This again means at least 10,000 tons more ore handled by the railroad company, at very little additional cost. And this gain will go on enlarging in geometrical ratio, until one road can not transport our entire product. I have facts in abundance to support my claims.

The saving that may be justly anticipated from lower smelting charges is manifestly very small, under the prevailing circumstances. The reasons for this conclusion will be much more apparent and convincing to the professional metallurgist, of course, than to the public, which looks upon smelting as the simplest of all manipulation, requiring only capital and ordinary labor. But it is to these same skilled engineers that we must turn for guidance out of the dilemma. The condition of the lead market will enforce a partial suspension of production, which will undoubtedly enhance the cost. This will cause the smelters to refuse the least desirable ores, and to seek such qualities as will flux themselves. Mines remote from market will shut down for a time; and while the supply of ore exceeds the demand, the reducers can get what they require at very low prices. A reaction will follow from the gradual stoppage of the supply, schedules will run up, and smelters will find competition very close. It will then be apparent that only by the most skillful management can ores be reduced at a profit. Here will come into play the inventive faculties of the metallurgist, and he who most successfully treats the waste materials and most closely utilizes the by-products will reap the richest rewards.

To us, the most beneficial results will accrue from the savings in railroad freights and in ore reduction; for what we expend each year in these items is all passed out of the district, while the cost of mining and of local transportation is applied where it will enter into circulation at home. It therefore becomes a matter of the highest importance to us to know if the railroad and the smelter are reaping undue rewards from the products of our mines, upon which we have lavished faith and capital, while they are handling them wholly without risk. Slovenly and wasteful methods will not long be tolerated in American metallurgy.

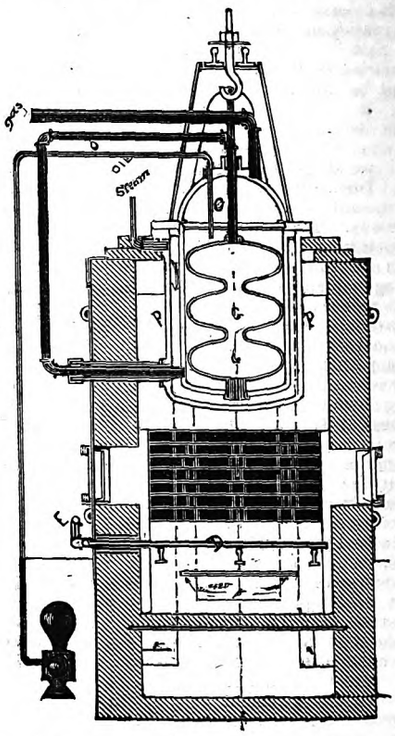
Taking all these points into consideration, I believe the outlook of the San Juan country for the coming years is not only bright and hopeful of itself, but we have still further chances of progression arising from the acknowledged fact that our formidable rival, Leadville, is losing her *prestige* as a carbonate field, and is beginning to put out an increased amount of sulphide ores, which, like ours, require a preliminary roasting.

SILVERTON, COLO., Dec. 18. THEODORE B. COMSTOCK.

AUTOMATIC COAL MINER.—An automatic coal miner, consisting of four horizontal reciprocating picks, delivering 250 blows a minute, is building at Pottsville. A scraper chain is connected with and follows each pick or cutter, and removes the cutting as fast as made. The machine will cut a gap 6 feet forward, 4 feet across the face of the coal, and 4 inches high without being moved. It can be easily managed by one man, and can be set at any angle. The motive power is compressed air, but electricity may be used.

CHESAPEAKE & OHIO CANAL.—Shipments by the Chesapeake & Ohio Canal closed for the season December 15th, although a few boats may leave this week. The water was to be shut off December 22d. The season has been a very good and prosperous one for the canal. From information obtained at the collector's office, it appears that during the season which just closed, 6288 boats, carrying 707,466 tons of coal, cleared from this port. The tonnage is over double that of the previous season (1882), when only 316,648 tons of coal were shipped from this point by canal. The gross amount of revenue collected at Cumberland during the season was about $300,000. From this, will be deducted a number of items, including wharfage, etc.

DIAMOND COMPANY (LIMITED).—Roswell W. Keene, of No. 10 Wall street, has filed with the Secretary of State a certificate of incorporation of the Diamond Company (Limited), for the purpose, as set forth in the prospectus, of "mining diamonds and other precious stones, the cutting and working, purchase and sale, the selling and loaning of the same for the purpose of gain and profit and the cultivation of art." The capital stock of the company is placed at $2,000,000, every dollar of which has yet to be subscribed. The other incorporators are Eunice Keene and Marian E. Keene, of Brooklyn, Henry J. Turner, and Sarah C. Turner. Roswell W. Keene says he spent a year in the South Africa diamond-fields, and is convinced that money can be easily made by buying diamonds there and selling them here.



PETROLEUM AS A FUEL IN IRON MANUFACTURE AND METALLURGY.

In our report of the visits of the members of the American Institute of Mining Engineers to the Norway Iron-Works, at the time of the Boston meeting, we referred at some length to a series of experiments carried on to utilize petroleum as a fuel for heating and puddling-furnaces. These have since progressed so far that the Vapor Fuel Company has now come before the metallurgical world with details of the apparatus used.

The generator of vapor fuel is termed the "thermogen," and is simple in construction and operation. It consists of two retorts of the best cast-steel, tightly elbowed together at the top. Within the inner retort are two globes, also of cast-steel, while surrounding the whole and resting upon a base of brick-work, as shown by the accompanying cut, is the apparatus complete.

The crude petroleum is kept in tanks situated at some convenient point outside of the works underground. The method of producing "vapor fuel" may be briefly described as follows: Steam is forced between the two retorts, is superheated, and thence passes into the lower globe within the inner retort and then into the upper, heating them both intensely. A small force-pump connected with the "thermogen" forces the oil through a small pipe, entering above the upper globe, upon the surface of which it falls in a fine spray. This globe is generally so intensely heated by the steam that has passed through it as to vaporize the oil instantly. Then the steam, which has passed out of the "thermogen" through a pipe extending from its top around on the outside to its base, re-enters, and, mingling directly with the gas, acts as a carrier, taking it through a pipe from the top of the retorts to the furnace.

Vapor fuel is in use at the Norway Iron-Works for boiler-heating, for

puddling, steel-making, and reheating furnaces; and so admirably does it perform its work (on the largest scale), that it is considered by the officers of the company and by the workmen to be not only the equal of coal as a fuel, but its superior. For a new process to quickly win its way with metal workers, who have been deceived many times by fine theories proving impracticable, is a strong indorsement in itself. Although adapted to an innumerable number of purposes, vapor fuel is possessed of especial value for metallurgical purposes; and if the experience of the Norway Iron-Works is a criterion to estimate by, there is no known fuel that will compare with it for the smelting of ores in reverberatory furnaces. In many parts of the country, it costs less than coal, it will save three quarters of the wear and tear of furnaces incidental to the use of coal in the latter, it is easily regulated and under control, it affords a high heat at a moment's notice, gives off no dangerous or disagreeable gases, and there are no ashes or *débris* to be removed where it is used.

One man can operate a "thermogen" with ease, acting as both engineer and fireman, and start a flame that has a heat of 6000 degrees Fahr., or over, in one minute, and yet with the turning of a valve can extinguish it entirely or reduce it to the extent that the exigencies of any operation may demand. Vapor fuel has already gone into operation in several extensive iron, steel, and copper smelting-works, and preparations are rapidly perfecting in half a dozen of the largest iron-working concerns on the continent for its introduction. When applied to steam-raising, it requires no radical changes in the setting or construction of boilers, and can be applied with the loss of but little time to any class of boilers in use. Its capability of providing an intense heat and the perfect control with which it can be handled and its cheapness are the chief claims for "vapor fuel", as well as the saving of the labor of firing and the handling of coal and ashes; while its obviating the necessity of cleansing grates is held to be a strong point in its favor. The use of vapor fuel for the reheating of steel ingots and blooms and similar work is said to be equally satisfactory. When applied to steel-melting, however, its merits are held to be still more conspicuous, no expensive alterations of a coal-gas furnace for the introduction of vapor fuel being necessary.

The cost of a vapor fuel plant doing the same work as a coal-gas plant

Digitized by Google

is claimed to be one tenth that of the latter, while it also insures a great saving in labor (as well as cost of fuel), one man with a thermogen doing the work requiring a dozen men by the older method. It is stated that comparison has proved (at the Norway Iron-Works) that in a year's use a vapor fuel furnace does 25 per cent more work than a coal-gas furnace, and at the end of that time is in a much better condition.

The Vapor Fuel Company, of Washington, was incorporated in February, 1882, under a special charter granted by the Virginia Legislature.

THE BAROMETER AN UNRELIABLE AID IN FORETELLING STRIKING VARIATIONS IN THE PRESSURE OF GAS IN OLD WORKINGS.

The results have just been published in England of one of the most valuable series of investigations yet made upon one of the many questions bearing upon the issuing of fire-damp into mine workings from old workings. These investigations were placed before the North of England Institute of Mining and Mechanical Engineers by Mr. V. W. Corbett, at its meeting at Barrow-in-Furness in July last. They were the outgrowth of the great explosion at the Seaham colliery on the 8th of September, 1880, which occasioned the loss of 164 men and boys. The workings were found to be on fire, and stoppings were therefore put in to cut off certain parts of the workings. The sealed workings therefore became a vast reservoir, several hundred acres in extent, and Mr. Corbett made use of the occasion to endeavor to ascertain whether there was any relation between the pressure of the air as revealed by readings of the barometer and the fluctuations in the pressure of the gas in these workings, as shown by the readings of water-gauges. Observations concerning the issuing of the gas were also made in a gallery about 50 yards long, connected with the sealed workings. It was used in much the same way as the tube of a barometer, to indicate the distance from the waste at which gas was found in the gallery, a man going in every hour with a safety-lamp to note the distance from the waste at which he first observed gas in the lamp. For seven months, all the observations, with three barometers, three thermometers, four water-gauges, and the "gas-check" in the gallery, were made hourly, and have been plotted by Mr. Corbett in a series of highly instructive diagrams. Three instances of great fluctuations of the pressure of the gas in the workings were observed, extending at times over from six to nine days. In no case did the barometer readings furnish any early warning of the coming of an influx of gas from the sealed-up workings. On the contrary, the barometers were found to fall at times when the pressure in the workings, as indicated by the water-gauges, was rising. In some cases, the beginning of the corresponding upward movement of the barometer was delayed from thirty-five to forty hours. The barometer appears to recognize only general or clearly defined great fluctuations, and even then slowly and tardily. Mr. Corbett's mass of data, in our mind, furnishes a striking proof that the barometer is a very poor and unreliable aid in foretelling any striking or alarming variations in the pressure of gas in old workings. It is true that the objection has been made that the existence of a mine-fire in those workings to some extent vitiated the results, and that only proof furnished by an analysis of the gas issuing from them could set them at rest. Still, even with that doubt hanging over the investigations, they are strongly confirmatory of the opinion long held that, long before the barometer indicates any change, the gas in the galleries of a mine may have come and disappeared. The elaborate tests by Mr. Lindsay Wood on the presence of gas in solid coal have dispelled the notion that there is any close connection between the issue of fire-damp from fresh openings and the atmospheric pressure. Therefore most mining men will abandon the long-cherished hope that the barometer can be of any material aid to them in guarding against the loss of life and destruction of property due to colliery explosions.

IN a paper on Coal-Gas and Gas-Engines, by F. Fisher—*Dingl. Polyt. Jour.* 249,178—the author analyzed the gas employed in driving a six-horse Otto engine, and found its composition to be as follows: Benzine, 0·69; propylene, 0·37; ethylene, 2·11; methane, 37·55; hydrogen, 46·27; carbonic oxide, 11·19; carbon dioxide, 0·81; nitrogen, 1·01; oxygen, trace; total, 100. With the engine running at a low speed, the gaseous mixture, after explosion, contained 2·4 per cent CO_2 and 17·2 per cent O; at high speed, after explosion, 6·5 per cent CO_2 and 9·9 per cent O, the temperature being 400 degrees C. It is therefore evident that the quantity of air taken in by this machine is from two to four times the volume necessary for complete combustion; and further, that gaseous mixtures much poorer in combustible constituents than ordinary coal-gas may be used in place of the latter.

THE NEW TELEPHONE.—Experiments were made recently on the large wire of the Postal Telegraph Company between New York and Meadville, Pa., a distance of 509 miles, with a telephone devised by Prof. Webster Gillett, of Ypsilanti, Mich. Owing to the storm and atmospheric conditions, the magneto bell was kept jingling by the induction alone, but there was little difficulty in carrying on a conversation. What Professor Gillett calls a 10-point instrument was used. He uses in his transmitter a needle attached to a rubber disk, coming in contact with granulated carbon, held under compression to increase the conductivity for taking up loss by friction and other causes. Most instruments have solid carbon buttons. Each point is like adding another telephone in power. The feature of the receiver attached to the telephone is the increased magnetic surface presented to the diaphragm. Chicago, a distance of 1010 miles, including a cable containing 22 wires, has been reached satisfactorily with the 10-point instrument. The single-point instrument has been operated for from 75 to 100 miles. The 10-point instrument was during the experiments reduced to six points, and communication was still kept up. The plan is to construct an instrument that will open communication by cable across the ocean as well as covering long land distances. A 20-point instrument is making for the purpose of ascertaining the distance it will reach. Professor Gillett stated that the French cable was 2486 miles long from end to end, and the resistance is 2·89 ohms. The resistance of the wire used during the next experiment was 1¼ ohms, but as satisfactory results have been obtained from the smaller copper wire, the resistance of which was 6 ohms.

SKETCH OF THE METALLIFEROUS DEPOSITS OF FLINTSHIRE AND DENBIGHSHIRE, WALES.*

(*Concluded from page* 385.)

In endeavoring to sum up the teachings of the foregoing, Mr. Davies says it may be safely inferred:

1. That the limestones, grits, and cherts, or the calcareous strata generally, of the two counties have, up to the present time, been more productive of the ores of lead and zinc, with their associated silver, north of the Great Yale fault and the group of mines connected with it, than they have been south of this point.

2. That, so far, the lodes have not, to the south of this point, been explored in the cherts, grits, and limestones lying above the main limestones, and that possibly in the future the lodes in these beds, as they lie over the limestones seen in the great escarpment of the Eglwyseg rocks, may prove productive of ores, as they have northward.

3. That the metalliferous deposits are confined to certain zones, or groups, or clusters of strata as defined in the foregoing pages.

4. That the productive parts of the lodes follow these strata down the course of their dip to the southeast, and that in this direction they may be followed and worked so far as draining and pumping facilities will allow.

5. That the last inference is especially applicable to the lodes that are on lines of great displacement of strata, the minor lodes dying out in this direction.

6. That the most permanently productive mines have been worked along east and west lines of displacement of the strata.

7. The fact that lodes are productive in certain groups of strata must be borne in mind in following and exploring a lode from a known productive point along its course.

The exceptions to this rule are (1) where a lode like the Minera is on a line of great displacement, and productive beds on one side of it are brought opposite to unproductive beds on the other, when the result will probably be productiveness in a less degree. Or, if the lower limestones are brought against the middle limestones, the result will probably be only a very slight diminution of productiveness. (2) When the beds are brought up to the surface on an east and west line by faults. In this case, the lode may be expected to be productive at two points, and at the same depths, because the productive beds have been thrown up by the fault.

8. That the great north and south faults are not productive of ore in commercially profitably quantities, except when numerous east and west lodes intersect them, and that, as a rule, the lead ore from these lodes is not of so good a quality as that from the east and west lodes.

9. Nevertheless, it would seem that these north and south lodes have in some way contributed to the productiveness of the east and west lodes, inasmuch as these last are richer in their vicinity. Probably they have facilitated the passage of water charged with metallic ores into the east and west lodes, which has deposited its burden before it has penetrated very far into the latter.

10. That in "flats," or "flat lodes" charged with clay, silver is not so abundant in the lead ore, and zinc is nearly altogether absent.

11. That the formation of "swallows" and such like cavities in the limestone beds as are now charged with clay and lead ore is of a subsequent date to the formation and filling of the east and west lodes containing the ores of lead and zinc, as proved by the fact that the swallows and pockets cut through the limestone with their lodes, which are now seen standing on either side of such cavities.

12. Therefore, the lead ore contained in the flats is of a newer origin than the lead ore in the north and south lodes, as is evident from the last inference, and also from the fact that the filling of the cracks and cavities with both earthy and metallic matters must have taken place after the cracks and cavities themselves had been formed.

13. The date of the filling of the east and west cracks of displacement is subsequent to the deposition of the Coal Measures, and probably before the deposition of the Triassic or New Red Sandstone beds, because the cracks run through and displace the Coal Measures, but are covered over with red sandstones of the Cheshire plain. The absence of fragments of the Coal Measures in the cracks, and the subsequently formed cavities, seem to point to an extensive denudation of the upper portion of the Carboniferous strata from off the lower before the cracks and cavities became charged with their metallic and other contents.

14. The cavities themselves seem to point to the ridges and beds of limestone lying for a long time within tidal and flood action. The original cracks were widened, and caverns scooped out, by the long-continued action of water. This condition of things was followed by the depression of the limestone beds into deeper water, in which gradually they became filled with the materials they now hold, such materials being subjected to chemical and mechanical agencies, by which they were dissolved out of the original rock, carried to their destination, and there sorted and deposited according to their specific gravity and chemical affinity.

But these last two paragraphs have carried us into the domain of the theoretical and speculative, and they have led us to forestall somewhat the answers that should be given to the questions, Whence were the ores of lead and zinc originally derived? Whence did they come into the fissures of the limestone? How did they come there? During what period or periods did they become fixed in their present position? And what were the principal agents to which their deposition in their present form is due?

On all of these questions there may exist, in the present state of our knowledge, considerable difference of opinion.

1. It may be safe to start with the assumption that the rocks of the earth's surface has been formed and re-formed, again and again, by the wearing down of previously formed, collected, and deposited matter,

* Abstract of a paper from the January, 1883, number of *Y Cymmrodor*. By D. C. Davies, F.G.S., author of *Metalliferous Minerals and Mining; Slate and Slate Quarrying, etc.*

Digitized by Google

such depositions have, from time to time, been aided and effected by emissions and ejections of matter from the interior of the earth, in the various conditions of gases, vapors, liquids, and solids, even as such emissions and ejections are taking place now in volcanoes, geysers, and springs of water charged with calcareous and other substances, both terrestrial and sub-marine.

3. It is inferred that in the seas in which our limestone beds were deposited, such emissions of calcareous matter were very abundant, that the origin of the great bulk of the calcareous matter of the strata is to be sought for in this source; the shell beds, the earthy matter of the impurer limestones and the silica, and other substances of the sandstone and cherty beds, being derived from the wearing down of older rocks, together with some portion, doubtless, of the calcareous matter.

4. That with the calcareous matter rising from the interior of the earth there came up also the metals, together with the substances with which, as "ores," they are now associated.

5. Confining the observations now, for a time to lead: this metal may have come from the earth's interior in two forms—first, in a pure and gaseous form, to be mixed with and held in solution by the waters of the sea for a time; or as mixed with carbonic acid—as carbonate of lead. Judging from the abundance of carbonic acid present in these early waters, it is reasonable to think that this last was the prevailing form. Indeed, it is difficult to conceive of the mineral remaining for any length of time in a pure state, surrounded as it would be, from the beginning, with other substances with which it would readily combine. With the lime also so largely present, it would be deposited upon the sea bottom, and thus form an integral part of the subsequent rock. But, just as in the clay pockets the carbonate of lead lies in the lowest place, it would, from its specific gravity, sink as low down in the calcareous ooze or mud of the sea as it could; and as now and again the continuous deposition of the calcareous matter was checked by the inflow of earthy matter from the land, as now marked by the shale or marl beds, the base of each bed or layer of calcareous ooze would be most strongly charged with the metallic substance. It would thus be in a favorable position to be taken up and carried off by the agent to be presently referred to.

6. After the whole series of the calcareous beds, with their interstratified shales, grits, and sandstones, were deposited, came the elevation of the whole out of the water, with the consequent drying and contraction, causing cracks, great and small, in every direction; followed by movements in the earth's crust, causing dislocations, shattering of strata, and innumerable cracks, besides the great movements to the south and east. These would, added to the original inequalities of the surface as the beds were lifted out of the sea, and consequent, in a great measure, upon them, be hollows filled with water and fed by rains; old channels and furrows to be widened and deepened by atmospheric and aqueous denudation; rain falling and water flowing and percolating through every crack and crevice. There would be long periods also when, now partly and now totally, the strata would be submerged in the sea, its water filling every chink and pore in the beds.

7. What was the agent, or what were the agents, by means of which the ores became fixed finally in the depositories where they are now found?

Negatively, the agency of heat to any great extent in the operation must be dismissed. It has been suggested occasionally, that the presence of rocks of a supposed igneous or metamorphic origin near the region of mineralized limestones, has had much to do with the deposition of the metallic ores. It does not seem, however, as far as the strata of the district we are considering is concerned, to have been the case.

That the principal agent was water must have become apparent. It is along water-courses that the ore is deposited. It is in cavities and recesses, where the flow of water has been temporarily checked, that the ore has accumulated. The quantity of the ore lessens usually in proportion to the distance reached from the great water-courses. The earthy fillings of the lodes and flats are aqueous deposits, and the ores of lead and zinc are interstratified with these. The accretions of ore in the flats are rounded by the action of water.

It is water, therefore, that, filtering and percolating through the cracks and interstices of the strata, has taken up and carried off, along with other materials of the bed, the metallic ores, until, reaching points where the flow was less rapid, where natural intercepting tanks and slime-pits, so to speak, existed, the metallic burden of the water held in solution or suspension would be deposited.

In water so strongly impregnated with various mineral matters, it is also probable that chemical action would be facilitated in places, and precipitation effected. The chemical action, taking place both when the minerals were first dissolved out of their parent beds, and when taken forward by the water, might be assisted by the temperature of the water, and it is possible that movements in the strata themselves, and those adjacent, with the intrusion near them of igneous rocks, might both generate heat, and also cause the emanation of gases that would assist both in the dissolving and taking up of the minerals and also in their subsequent deposition.

Then the different beds themselves would have different temperatures. They would also possess different degrees of magnetic or electric power. For, although as yet not much is known of the way in which magnetic currents have affected the deposition of metallic ores, it is known that these currents have done much in giving these ores an east and west direction, and in determining the points at which they should be precipitated from their watery solution.

8. Mechanically speaking, the crack, limited in size, in the lower limestones, may have been partly filled with earthy minerals before the great flow of mineralized water commenced. In the upper limestones, the abundance of shaly matter would soon fill up the cracks, and the intervening shale-beds would effectually close them to the flow of water, so that the absence of metallic ores from these beds is partly accounted for in this way.

9. Still the shale-beds and the fossiliferous limestones have had much to do with the change, almost universal, which has taken place in the lead ore from its early condition as carbonate of lead, and its other early combinations and forms, to sulphide.

These beds consist largely of organic matter, so strongly charged with sulphur that the fossils have in many cases lost their original material, and become lumps and masses of pyrites. Water flowing over and through these beds becomes charged with sulphureted hydrogen. A sulphurous bed of fossils at Dyserth is a good example of this. Chemists know that, when manipulating with this gas, the surface of the lead-fittings in their laboratories becomes altered into a sulphide. Here, then, is the agent, or at least one chief agent, by which the carbonate, nitrate, silicate, or other early conditions of the mineral have become converted into a sulphide as it is now found. It must be remembered, also, how largely present sulphur is throughout the whole of the limestones, and still more so in the overlying Coal Measures. The powerful decomposing effect of water containing carbonic acid, such as in places the waters of the carboniferous seas would be, upon the silicates of minerals, is also well known; and here is indicated an agent whose influence would be active on the mineral contents of the beds of sandstones at the summit of the group.

10. This operation can not be limited to any one time. It is a process that might have gone on as the materials were deposited. Subsequently, for long periods, the water flowing through and by the fossiliferous limestones, shales, and coal-beds would carry on the process. In water, also, previously charged with plumbiferous matter flowing over these beds, the change to sulphides would take place.

11. It will be seen that zinc was present in large quantities as well as lead, in those early waters, and, to a considerable extent, the remarks just made apply to its deposition also, as well as to the changes it has undergone. The ores became deposited together, occupying, to a large extent, the position their different specific gravities would assign them.

12. During the latter period, when the galena of the flats and pockets was deposited, zinc appears not to have been present in the waters of the sea. That the galena was derived from the material existing in the water, and not from the wearing away of the older ore-deposits in the limestone or in the older Silurian rocks, is proved by the fact that zinc, which is so largely associated with lead in the lodes of these strata, is altogether absent. The separate origin is also proved by the greater absence of silver from the lead ore of these newer deposits.

Various modifications and additions to the processes whose outline has thus been sketched will very likely occur.

ANOTHER POSSIBLE CAUSE OF BOILER EXPLOSIONS.

M. Vignes, in the *Journal la France*, draws attention to experiments made as long ago as 1846, by Professor Donny, of Ghent, and intended to show the influence which air exercises on the boiling-point of water and on the character of its ebullition. In this experiment, ordinary water is placed in a clean glass tube, open at one end, and boiled long enough to drive away not only the air above the surface of the water, but all the air dissolved in the water. Then, when the upper part of the tube is full of pure steam, the mouth is hermetically sealed and the tube is left to cool. When cool, it is about half full of water, above which is vapor of water at a very low pressure. The tube being thus prepared, its lower end is plunged into a bath of glycerine or oil, which is gradually heated. No ebullition is visible in the tube when the temperature reaches 234 degrees Fahr. At 240 degrees Fahr., however, the column of water bursts, as it were, in two, with a sudden explosion, and part of it is flung against the sealed end with such force as often to break it open. Now, in industrial works, it often happens that a boiler, having been filled with water, works for three or four hours without receiving a further supply. It may then be cooled down, and the next time it is wanted it may very probably be fired up again without starting the feed-pump, the water-level being judged sufficiently high; but the water in such a boiler will be in the same condition as that in the test-tube; that is, it will be deprived of all air, and consist of water below and vapor above, the latter, however, being probably at a much higher pressure than that of the water in the tube. This water has no free surfaces in its interior due to the presence of bubbles of air, from which evaporation can take place. Consequently, as in the test-tube, there will be delay in vaporizing—at least, until the expansion becomes great enough to overcome the pressure of the superincumbent vapor, and a sudden flashing into steam, which will be of the nature of an explosion, and may easily overcome the resistance of the boiler. The pressure thus attained may be very great. In the test-tube, the pressure of the temperature of explosion—240 degrees Fahr.—will be eighty-six times what may be taken as the pressure of the superincumbent vapor in the boiler, as already observed. That pressure will probably be much higher, and the pressure of the explosion will probably be much higher also. To avoid this source of danger, it will be sufficient, as M. Vignes points out, to make it a rule always to feed a boiler when it is fired up after standing. This will have the double effect of lowering the pressure and of facilitating evaporation, by distributing the mass of water in the boiler, and charging it to some extent with bubbles of air. Meanwhile, the facts he has adduced are certainly sufficient to warrant a belief that we have here a key to many cases of boiler explosions which have hitherto been wrapped in mystery and it seems very desirable that careful and precise experiments should be undertaken to prove or disprove the production, on a large scale, of the phenomena thus shown to exist in laboratory experiments.

JOHN HUGHES DEWEES, who died at Thomasville, North Carolina, on the 7th of this month, was born at Trappe, Montgomery County, Pa., on the 26th day of February, 1831, being the oldest son of Dr. Jacob Dewees, from whom he inherited a fondness for scientific pursuits. He began life as a civil engineer on the Chester Valley Railroad, and was subsequently employed under Kimber Cleaver in the location and construction of what is now the Shamokin division of the Northern Central Railroad. After its completion, he remained in the Shamokin region, giving his attention to mine engineering and geology, and became extensively engaged in the mining of coal. In 1874, having received the appointment of Assistant State Geologist, he made a thorough examination of the iron ores of the Juniata District. One volume of his report has been published for several years, and the other is now in press. In 1879, he resigned his position, since which time he has been engaged in general professional work.

CABLE SYSTEM OF TRANSPORTATION.

A proposition was recently made by the National Cable Railroad Company, of this city, to the Brooklyn Bridge trustees, to take charge of the cable transportation over that structure. In regard to this proposition and other matters of detail, President William P. Shinn recently made the following statement:

The cable system of transportation was first put in operation on street railroads by Mr. A. S. Hallidie, in San Francisco, in 1873, and has since been extended so that it is used on nearly all the street roads in that city. In 1881, the system was adopted by the Chicago City Railroad Company, and twenty miles of cable have been in successful operation there for nearly two years. The use of cable for transportation has been carried on for many years in connection with mining operations, but Mr. Hallidie was the first person to successfully apply it to the transportation of passengers in the streets of a city. His patents and others which are now controlled by the National Cable Railroad Company, of this city, cover the only complete system that has been put into practical use, and the patents have been broadly sustained in the United States courts in California. The National Railroad Company has been organized with power to build, own, lease, and operate street railroads with cable power. It proposes to begin active operations at an early date. The company has made a proposition to the trustees of the Brooklyn Bridge to transport over that structure a maximum of 6000 passengers an hour in each direction within sixty days after being put in possession; and the company further agrees, whenever the necessary terminal facilities shall have been provided by the trustees, itself to provide the additional facilities necessary to the transportation of from 15,000 to 20,000 passengers an hour in each direction. Complaint has been made that so little use is made of the bridge. The distance—about a mile and a quarter—is too great for many persons to walk, especially in hot, cold, or otherwise unfavorable weather, and the irregularity with which cars have been running does not invite travel by that route. To bring the bridge into general use, it is absolutely essential that cars should be run promptly, frequently, and with certainty. This the company proposes to do if its proposition is accepted. The proposition looks to an immediate reduction of the fares from five to three cents, and a further reduction to two cents whenever the bridge is made free by the Legislature. With a fare of two cents, and tickets in quantity sold at a somewhat less price, there is no reason why the Brooklyn Bridge should not be made the great artery of communication between the two cities.

President Shinn, according to *Mechanics*, further stated that he had not yet been officially advised that any action had been taken, newspaper reports being to the effect that the proposition was laid on the table without debate. It was also reported that no action had been taken because the terms were unsatisfactory. The company made a plain business proposal to do upon the bridge what has not been done and what did not seem likely to be done. The terms as to details were, of course, proper matters for discussion and amendment, if necessary. As to the use of the Hallidie patents in Chicago, it was remarked that building was begun in that city without these patents; but it was soon decided that it would be best to obtain the right to use them. which the Chicago company proceeded to do, and the road is now constructed and operated under that system. It may be of interest to here state that a road operated by the Hallidie system is already in use in Liverpool, and another company has been authorized to construct one in London.

DRAUGHT-TUBES OF TURBINES.

In a paper on the water-power of the Falls of St. Anthony, read by Mr. J. P. Frizell, at the annual convention of the American Society of Civil Engineers at St. Paul, Minn., we find the following passage, which is worthy of careful consideration:

A conspicuous instance of the misuse of power is furnished by the draught-tubes with which almost every wheel is provided. The usual arrangement of the wheel is this: A vertical shaft is carried well down into the limestone. A shelf or ledge is there left around the shaft, and the latter is carried with diminished diameter through the limestone and to the necessary depth in the sandstone. On this shelf, rests the platform which supports the wheel. The water is discharged from the wheel through a draught-tube, which reaches down below the surface of the water in the wheel-pit. The water thus acts not directly, by its weight above the wheel, but indirectly, by diminishing the atmospheric pressure below the wheel. These draught-tubes are almost invariably too small. I give a few instances:

A 54-inch "New American" turbine, acting under a head of 48 feet, has a draught-tube 52 inches in diameter. The wheel is stated by the makers to discharge, with full gate, 216·45 cubic feet per second under a head of 40 feet. The effective head, as we shall see, is about 44 feet, and consequently the discharge with full gate should be 227·27 cubic feet per second. This would require a velocity through the draught-tube of 15·41 feet per second, corresponding to a head of 3·69 feet. Adding the frictional head in the draught-tube, assumed to be 24 feet long, we have 4·10 feet for the loss of head at this wheel, or about $\frac{1}{12}$ the total power of the wheel. With the wheel running at full gate, this loss amounts to 1·4 mill powers, worth commercially some $1400 per annum.

In another mill, the proprietor is now putting in a 40-inch Victor wheel, to work under a head of 43 feet, provided with a draught-tube 40 inches diameter. We shall find the effective head here to be a little over 37 feet. The discharge, under a head of 37 feet, is given by the makers as 155·3 cubic feet per second. This implies a velocity of 17·8 feet per second in the draught-tube, involving a loss of head of 4·92 feet. Adding 0·59 feet for the fractional loss of head in the draught-tube, assumed to be 20 feet long, we have for the total loss of head 5·51 feet, or something over one eighth the total power of the wheel. These are only two instances taken at random, and might be multiplied to any extent.

The waste of power is not the only evil result of this gross disregard of the laws of hydraulics. The inordinate velocity with which the water is discharged from the draught-tube is very destructive to the wheel-pit. On one occasion, a miller had used his raceway for a common sewer of his mill, a use which rendered the wheel-pit tolerably safe from inspection. Having occasion to visit it, he found a cavity under the draught-tube some 30 feet in depth. Nothing disconcerted by so trifling an accident, he filled up his pit and set his mill to running again. But when the owner of the adjoining mill, in attempting to deepen his race, pumped up materials recognized as coming from the above-mentioned pit, it was felt that the limit of safety had been reached, and the latter enterprise was discontinued.

Some of the millers, with a praiseworthy determination not to be beaten in this combat with the laws of nature, have lined the bottoms of their wheel-pits with boiler-plate. If they would put sufficient iron in their draught-tubes, I think they would have no occasion to use that material in their wheel-pits.

FURNACE, MILL, AND FACTORY.

The Stillwell & Bierce Manufacturing Company, Dayton, Ohio, manufacturer of turbine-wheels and feed-water heaters and purifiers, has completed two additions to its works—one 76 by 40 feet and the other 40 by 60 feet—by which it will increase its capacity one third.

The Deane Steam-Pump Company has just shipped a low-pressure pump having a capacity of 3000 gallons per minute. It was built for a party in New York State, and is to be used for irrigating purposes. The discharge-pipe required is 18 inches in diameter.

The Gates Iron-Works are shipping a 500-ton crusher to P. M. & J. F. Shanley, Newark, N. J., and one 100-ton crusher, with elevator mounted on wheels, to the Hopes Artificial Stone Company, Baltimore, Md.

Jones & Laughlins, of the American Iron-Works, are preparing to experiment with the Fuel-Gas Company's natural gas in a few of their puddling and heating-furnaces. If the result proves to be satisfactory, they will use the gas in all their furnaces instead of coal. These works contain 76 puddling-furnaces, 3 scrap-furnaces, and 30 heating-furnaces.

The Laclede Wire and Fence Company, of St. Louis, recently incorporated with a capital of $10,000, has purchased the wire and machine works of Butterfield Brothers & Co., in that city, the latter company retiring from business. The purchase represents an investment of something like $16,000, and this outlay will be increased to about $20,000 before the beginning of the new year by the buying of additional machinery for the works. The stockholders of the new company are: Charles L. Merrill, President; Paul Robyn, Vice-President; W. D. Van Blarcom, Secretary and Treasurer; and J. C. Van Blarcom, present cashier of the Bank of Commerce. The board of directors consists of the three officers named. The business of the new concern is the manufacture of barbed wire and the handling of plain wire of all kinds.

The pool of the tube manufacturers has finally been formed, and the prices will be increased. The principal firms of the new combination are: Morris, Tasker & Co., of Philadelphia; the American Iron and Tube Company, of Middletown, Pa.; the Lake Shore Tube-Works, of Cleveland, O.; the Reading Iron-Works, of Reading, Pa.; National Tube-Works, of McKeesport, Pa.; Spang, Chalfant & Co., of Sharpsburg, Pa.; and the Pennsylvania Tube-Works, of Pittsburg.

It is stated that the Pottstown Iron Company contemplates erecting a large universal plate and shape mill on its grounds.

Notices have been posted in the several departments of the Steelton mills announcing a reduction of wages and a slight reduction of force, to take effect January 1st. The reduction in wages will not affect the outside laborers or those who are now making $1.20 per day.

The 10 per cent reduction offered by Graff, Bennett & Co., at the Clinton mills, Pittsburg, to the engineers and laborers has been compromised by the engineers suffering only a 5 per cent reduction and the laborers 10 per cent, with the understanding that they will receive their old wages as soon as the price of iron advances sufficiently to justify the firm to make the increase.

Notice was given on Saturday night for the closing indefinitely of the Philadelphia & Reading Coal and Iron Company's rail mill at Reading on January 1st. Three hundred hands will be thrown out of employment. The cause assigned is dullness in the iron trade. This mill makes the largest part of the rails used by the Philadelphia & Reading Railroad Company, and also furnishes rails to other parties.

A few years ago, a Swedish captain of engineers had charge of some harbor work, but failed to carry it out in the specified time because the explosives at his command were unsuitable. He asked and obtained six months' time to experiment on explosives, and during his investigations invented "forcite." This explosive, winning rapid favor in Europe, attracted the attention of gentlemen for a long time identified with the manufacture of nitro-glycerine powders on the Pacific coast, the outcome being that works were put up by the American Forcite Powder Manufacturing Company at Lake Hopatcong, N. J., under the management of Mr. M. Eissler. The editor of the Dover *Iron Era* has recently visited the works, as yet not quite finished, and from his long description we take the following data. The machine-house is a large brick structure, 44 by 84 feet in size, divided into four rooms by brick walls running up to the gable, and making each compartment separately fire-proof. In the first room are the large steel tubular boilers of 75 horse-power, substantially set in masonry, which furnish the power and steam for the purposes of the whole works. The second room contains an Ingersoll duplex air-compressor and air-receiver; a handsome 25 horse-power engine; one of Worthington's large force-pumps, having a capacity of 300 gallons per minute; also the boiler feed-pumps and heater. In one part of the third room is a repair-shop, fitted up with lathes and other tools for the repair of the machinery. The other part of this room is intended for the preparation of raw material, and the fourth room is designed for a like purpose, both containing a large amount of machinery necessary to the work. Throughout the whole building, the shaftings are arranged on independent bearings, in order to avoid all friction and loss of motion.

Building No. 8 is adapted to a new and novel feature in the manufacture of powder. It is a brick structure, 25 by 65 feet in dimensions, and contains the machinery and implements necessary for the regaining of the waste acids which remain after the manufacture of the nitro-glycerine. The apparatus consists of four very large retorts, each weighing 5000 pounds, for the reconcentration of acids, which are connected with condensing-towers, and a complete system of machinery necessary for the work to be performed.

The nitro-glycerine house is a three-story frame building, 32 by 32 feet in size. In the third story is the apparatus for the mixing of the glycerine. When this is accomplished, the acids are discharged in a series of vats, situated on the lower floors, where the processes of separation and purification are carried out. The whole work is done automatically by the use of compressed air, there being no individual handling whatever of the materials. As this building is situated twenty feet higher than the acid-regaining works, every particle of the resting acids are carried by gravitation through lead pipes to the acid-regaining works, where they are reconcentrated and sent back again by the aid of compressed air to the nitro-glycerine house and worked over and over again.

The nitro-glycerine is carried to the first mixing-house through large India rubber pipes, well protected and laid under ground. Here it is converted into the powder called forcite, for which superior advantages are claimed over the other powders.

From here, the nitro-glycerine is conducted in the same manner to the second mixing-house, which is sunk into the ground, to obtain the necessary grade to conduct the liquid by gravitation.

Still ascending the grade, the first cartridge-house is reached, where the powder is put into cartridges with the aid of two machines. There are two more cart-

Digitized by Google

ridge-houses of the same pattern, furnished with the same number of machines. In the first house, the machines are operated by a little upright engine, run by compressed air. The power for running the machines in the other two buildings is transmitted by wire rope from the engine in the first. From these buildings the cartridges are carried to the packing-houses.

The Ingersoll Rock Drill Company, of New York City, has furnished for the Washington Aqueduct Tunnel a compressor plant consisting of four improved Ingersoll "straight-line" air-compressors, having 24 by 30-inch cylinders; 6 100 horse-power boilers; 28 3½-inch "Eclipse" drills; 4 hoisting-engines, and 5 pumps, together with the necessary pipe, etc. The plant is located at a central point, and the air is carried five miles through 12, 10, and 6-inch pipes to the head of four shafts, where it is received by 4-inch pipes and supplied to 28 Ingersoll drills, hoisting-engines, pumps, etc. When the tunnel, which will be 4¾ miles in length, is completed, the air will have been carried through ten miles of piping.

Three thousand employés of the National Tube-Works Company, of McKeesport, decided to accept a reduction of from 12½ to 25 per cent in their wages after January 1st.

James Hooven & Sons and J. H. Boone & Co., iron manufacturers of Norristown, Pa., have given notice that on and after January 1st, 1884, the wages of puddlers will be reduced from $4 to $3.75 per day, and that the wages of all other employés will be reduced in proportion.

The Thomas Iron Company, at Hokendauqua, has given notice of a general reduction of 10 per cent in all wages, to take effect January 1st. This company has recently reduced its working force at least one third. The Crane Iron Company, at Catasauqua, has given notice of another reduction of 10 per cent, to take effect January 1st. This makes a reduction of 20 per cent by this company, which on Saturday further cut down expenses by discharging some of its hands. Nearly every furnace in the valley has reduced its wages. The Glendon Iron Company is an exception, though it has cut down production.

The Iron City Forging Company, a new concern, has completed its works at Sumner station, near Pittsburg.

The rolling-mill of Atkins Brothers, in Pottsville, Pa., has shut down for the present. The length of the stoppage is uncertain.

Etna Furnace, near Cave Spring, Ga., has gone into blast again after a short stoppage.

Clarksville has appointed a committee to visit Cincinnati and consider the proposition to move the Malleable Iron-Works, now operated in the latter city, to Clarksville. The proposition is, substantially, that Clarksville contribute $37,500 for a half-interest in the new enterprise to be established there, to which the company will add its plant, valued at $49,235.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY.

HERRING VS COPPER QUEEN.—The suit is one brought by Colonel Herring, administrator of the estate of his brother, Joseph Herring, against the Copper Queen Mining Company, to recover one third interest in the Copper King mine at Bisbee. A jury has been waived in the case, and a majority of plaintiff's witnesses have already testified. On the decision in this case, says the Tombstone *Epitaph*, hangs the title to still another third of this mine, for which Joseph Dyer, as administrator of his brother's estate, is sueing.

TOMBSTONE DISTRICT.

CONTENTION.—The pump started up December 10th, and since then the main shaft has been pushed ahead with all the vigor possible. It is expected that the level of the Grand Central shaft, which is 30 feet below the water surface, will soon be reached. All the machinery works admirably; in fact, better than expected. The mine was perfectly drained in about five hours, after which the pumps were run at less than half of their speed. While work is pushed ahead vigorously below the water-level, no less activity prevails in the upper levels, and the stopes are still furnishing the usual contingent of ore, and will in all probability continue to do so, after prospecting and development-work below the water has gone far enough to enable the management to extract sufficient ore from that region to keep the company's mill running at its full capacity.

DEFENSE.—A number of parties are at work chloriding on this mine. The mine appears to be literally covered by a net-work of ledges, some of them carrying ore exceedingly rich in silver. This mine has always been an excellent field for chloriders, and is now, as more depth is attained, if any thing, increasing in productiveness.

GROUND HOG.—The developments recently made will soon necessitate the erection of some reduction machinery.

GILA COUNTY.

OLD DOMINION.—A new 80-ton furnace, to replace the old No. 1, has been received. The company will soon have the three furnaces in full blast.

PINAL COUNTY.

COPPEROSITY.—This group of mines has been sold to San Francisco parties for $57,000. The Florence *Enterprise* states that they are situated about 35 miles south of Casa Grande. The group consists of the Copperosity, Welshman, Little Chief, and Copper Giant, all being on the same vein. The four claims take in 5200 feet in length by the usual width of 600 feet. Ore crops continuously for 4500 feet on the vein. It is the intention of the company, which will be known as the Casa Grande Copper Mining Company, to erect a fifty-ton smelter. It is stated that coke can be delivered at the mines for $22 per ton and all supplies at $6 per ton from Casa Grande. There is also a great abundance of wood in the immediate vicinity for fuel.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

Reports from this district show nothing of importance. Work goes on, and the production continues. It is stated by San Francisco papers that James S. Mowers has filed a complaint against John Pattie and sixty-eight co-defendants. Plaintiff alleges that as sheriff of Mono County he attached certain property of the Noonday Mining Company on a writ of execution issued by the Superior Court of the city and county of San Francisco, to satisfy a claim of Henry Wadsworth. That he as sheriff sold the said property at public auction, and that Wadsworth became purchaser at $7000, which $7000 Wadsworth credited toward the satisfaction of his judgment against the company. The defendants, as employés of the mine, have now brought claims against the sheriff for the recovery of wages due for services rendered. Plaintiff asks the equitable relief of court, and that said claims be decided adversely to defendants. Similar suits have been brought by the same plaintiff against the employés of the North Noonday Mining Company and the Red Cloud Consolidated Mining Company.

NEVADA COUNTY.

EMPIRE.—The shaft is down 1428 feet. Ore is raised from five different levels. It is of good milling quality, showing sulphurets in abundance and plenty of galena. There are now about 250 tons of quartz on the dump at the mill.

IDAHO.—The company has done a great deal of prospecting in the last year, and has made many important and valuable changes in its works. The lower levels of the mine are looking well, holding a good-sized ledge.

IMPERIAL.—Pumping continues, and it is expected that sinking will shortly be resumed.

MAGENTA.—Preparations for steady work have been made. The mine is now free from water.

PLUMAS COUNTY—GREENVILLE DISTRICT.

ARCADIAN.—The development made shows that the mine is a good one and that the prospects are very favorable.

GREEN MOUNTAIN.—Good progress is made in running the tunnel in the mine, and the indications are that, by the middle of January the Blake chimney will be reached.

COLORADO.

DOLORES COUNTY.

This has apparently been a dull season in the mines of this section, but the output is more than double that of the preceding year, when the various estimates placed it at about $125,000. The production is estimated as follows: Grand View Smelter, $135,000; Santa Clara Milling Company, $61,000; Rico Reduction Company, $12,000; ores not treated in Rico, $75,000. Total, $283,000.

RICO REDUCTION COMPANY.—This company will erect concentration-works on the West Dolores next year. The ores to be handled are the Little Susie, Little Wonder, Russian Bear, and other properties in which the company has an interest; but it will also do custom work for other claims.

GUNNISON COUNTY.

MOFFET SMELTER.—According to the *Review-Press*, this smelter remains a failure. The owner of these works came from the lead district of Missouri, and with a great flourish of trumpets announced that he would put up reduction-works and teach Colorado smelters a thing or two about argentiferous galena smelting. The works have been completed now for about a year, and have their first car-load of bullion to ship. Alterations and improvements have been going on ever since, yet the furnaces will not work.

ROSE & REED CONCENTRATOR.—This concentrator is kept busily running both day and night on Forest Queen ore, and it is more than likely that it will be busy all winter, on ore from this mine, as preparation to work all winter has been made.

HINSDALE COUNTY.

CROOKE MINING AND SMELTING COMPANY.—The properties have been formally delivered to the representatives of the English company. Extensive operations and improvements are contemplated.

LAKE COUNTY.

On an average, about ten cars of ore a day, amounting to about one million pounds a week, are shipped from Fryer Hill mines to Utah. The ore is shipped to the Horn-Silver, Mingo, Germania, and Morgan smelters. The reason for shipping the ores such a great distance is the fact that there is a better market in Utah for the class of ores shipped than in Colorado. The ores referred to are low grade, containing no lead, and from six to twelve ounces in silver to the ton. They carry, however, a large percentage of iron—not less, we believe, than forty-five per cent excess over the silica—and consequently are valuable to the Utah works for the creation of an economical slag, while the silver pays for the mining and a portion of the freight.

ELGIN.—The new furnace at the Elgin smelter was blown in on the 18th inst., and the establishment has three stacks in blast. The new furnace increases the capacity of the works forty per cent.

EVENING STAR.—The company's mines continue producing a limited amount of low-grade ore. While the resources of the mine are nearly exhausted, the property has so far more than paid all expenses, and notwithstanding the great amount of new work done, occasional transmissions of money are made to the New York office.

IRON HILL CONSOLIDATED.—The operations during the eleven months past—the time the company has been organized—show that the property has advanced very rapidly, until it stands very near the head of the list of large producing mines. The shallow shaft on the White Cap has been increased to a depth of 340 feet, and the forty feet of drifting in the property have been extended until at present there are over 6000 linear feet of levels, branching out into all portions of the territory and opening up extensive ore-bodies. The bare hill-side has been covered with shaft-houses, ore-bins, timber buildings, and work-shops. One twenty and one fifty horse power hoisting-engine occupy the place where formerly stood a Joplin whim and a windlass. A large building and good machinery have been placed on the Imes shaft, where there had been only a rattle-trap hoister and a primitive log cabin. In addition, about 16,000 tons of ore have been extracted and shipped to the smelters, and large resources opened. While working on the southern end of the property, the company shipped a great deal of high-grade lead ore. Recently, however, in pushing work from the White Cap shaft, the ore has improved to a remarkable extent in silver, and a large ore-chute has been opened, from which a hundred-ton lot settled for lately ran eleven one hundredths of an ounce in gold and thirty-three ounces in silver to the ton. The ore carries but thirteen per cent in lead. The mine is producing at the rate of about 2000 tons a month, and is employing one hundred and fifty men.

IRON SILVER.—The company's mines during the first eleven months of this year produced 85,154 (dry) tons of ore, which will make the entire yield of the mines for 1883 at least 92,654 net tons. The ore, the managing director states, will average over twenty-five per cent in lead. This makes a gross yield in lead of 23,163 tons, and places the Iron Silver at the head of the lead-producing mines of America, with quite a margin over the next largest producer, which is the Horn-Silver, of Utah.

LITTLE PITTSBURG.—During the month of November, the company netted above all expenses, $5000. The prospects for this month are not nearly as flattering, and the company will be fortunate if there is any margin remaining at the close of December, to be added to the cash resources. The ore-bodies that have yielded in the past were small, irregular, and unreliable, and the same is to be expected from those now opened. The only new work, warranting special mention, is the No. 10 shaft. This has lately been straightened up, and portions of it retimbered, placing it in working condition. The sinking of the shaft to greater depth will now be resumed, and it is possible, although extremely doubtful, that new ore-bodies will be found lower down.

LITTLE SILVER.—Recently a three-foot body of ore was opened, from which a lot has been shipped to the smelters and settled for on the basis of twenty per cent in lead and twenty-two ounces in silver to the ton. The ore is showing a marked improvement, as advances are made on the body, and assays have been obtained of from seventy-five to one hundred ounces. Considerable galena and carbonate ore is also discovered.

MIKE & STARR.—Exploration work is carried on. The workings continue in iron pyrites and zinc-blende.

ROBERT E. LEE.—Negotiations with English parties for this mine are in progress, and parties are now on their way here from England. The low-grade ore taken from the mine about a year ago, and which has just been shipped, shows that the ore has averaged fairly well in silver, the lowest return yet received being eighteen ounces to the ton, while the highest settlement was on a basis of forty-six ounces in silver to the ton.

ROSEVILLE-ALTA.—Mr. N. N. Robertson, manager of this company's mines, a short time since brought suit for $15,000 against the company for salary and money advanced and now due him.

OURAY COUNTY.

CINCINNATI.—The company is sinking two shafts and driving a long tunnel to connect with them, so that in the spring the ore in which they are now sinking can be stoped out without hinderance by water. The drift will, in all probability, connect with the first shaft by the middle of May. By this tunnel, the mine will be drained at an average depth of 100 feet below the surface; that is to say, it

Digitized by Google

will free 100 feet of back or stoping ground for its entire length of 1500 feet. The Cincinnati is a true fissure-vein, averaging in width about 12 feet between the walls and carrying from six to eight feet of ore-bearing quartz. It is in a trachyte formation of country-rock, and dips to the west, with a course about northeast, southwest; altitude, 11,250 feet above sea-level. The character of the ore is free or native gold associated with galena, copper, and iron pyrites, and zinc-blende in a matrix of white crystalline quartz and what is called here rose quartz, a silicate of manganese. On the surface, there is a great deal of the black oxide of manganese, but this disappears with depth.

SAN JUAN COUNTY.

Mineral Point has had a number of energetic citizens at work this year. James Boyce shipped considerable ore to Silverton for sampling and concentrating, from the British Queen, which carries large bodies of high-grade rock, running from 21 ounces to over 200 ounces in silver. George W. McIntyre sent a quantity of galena and pyritous ores, of shipping and concentrating grades. J. W. Cooper had some fair-sized lots of Chicago ore concentrated by Comstock & Co. quite profitably, after shipping fifteen miles to Silverton. A good concentrator in this locality might do a paying business. One is now established, but did no work last year. Other mines in the vicinity are the Old Lot, Maid of the Mist, Red Cloud, London, Mastodon, and the properties of the Waldron Consolidated Company. Some of these have also shipped this season.

Animas Forks is the center of a rich mineral district. Greenleaf's concentrator and that of the Eclipse Smelting Company are within easy reach. The latter has been running a part of the year. Another mill of the kind is projected for the Mastodon mine, in California Gulch. Some of the producing mines in this section are the Sioux City, Little Dora, Mountain Queen, etc.

Eureka has held back somewhat in anticipation of an extension of the railroad, but work has favorably progressed upon most of the mines in the vicinity. The Sunnyside and Ella mines have been the largest shippers. Developments have been made this year upon the Tom Moore, Byron, Hard Cash, Roving Ranger, Ben Franklin, Hidden Hand, Sunnyside Extension, Cuba, and others of the Niagara Consolidated Company.

Between Eureka and Howardsville, many claims have been worked, usually with encouraging results. The Middleton concentrator had poor success with portions of its machinery, but managed to get matters righted at the beginning of winter, so as to be ready for next season's business.

Howardsville and Cunningham Gulch have not fallen behind. The Highland Mary, Pride of the West, and Green Mountain lodes have yielded good results, and many other veins could produce largely, if systematically worked. The Howardsville concentrator shut down early after an unsatisfactory trial-run.

Silverton has grown materially since 1882, the population having more than doubled within the past year. Shipments, many of them quite heavy, have been made from the King Solomon, North Star (King Solomon Mountain), Round Mountain, Silver Lake, Nevada, Legal Tender, Aspen, Gray Eagle, Idaho, Empire, North Star & North Star No. 2 (Sultan Mountain), Emerald, Cleveland group, Zuni, and other properties. Three sampling-mills and one concentrator have been steadily running.

From Cement Creek, have come some of the most important shipments, though the district is newly worked. The Samson, Paul, and others have begun to produce a good quality of free gold ore, and rich galenas have been produced by the Galena, Uncle Sam, Climax, and McMillan lodes.

Poughkeepsie Gulch has sent high-grade contributions from the Bonanza, Alaska, etc., and the Columbia has shipped liberally.

Red Mountain has eclipsed all other districts in the amount of her shipments and in the number of mines producing. Among those which have furnished the largest part are the National Belle, which continues to improve in the lower workings; the Yankee Girl, Congress, Hudson, Enterprise, Treasure Trove, and numerous others which have yielded good ore from the start; the Excelsior, Silver Ledge, Turquois, Little Prince, and many more. The ore-bodies in this section are large and solid, being mainly the fillings of old hot-spring chambers. The cave in the National Belle is but one of the many already opened and yet to be discovered in that region.

Some good developments have been made in new districts, as in Mill Creek, near Chattanooga, in Ruby Basin, Pennsylvania Gulch, and Ice Lake Basin, the last three localities showing rich gold croppings. These points offer probably one of the best openings for capital, with intelligent selection and capable management.

Ophir still yields the best ores shipped to Silverton, as regards grade and quality. The Nevada, Caribou, Silver Belle, Santa Cruz, Grand View, and Pitkin have been the heaviest shippers, with smaller lots from the Mohawk, Crown Jewel, and others. One of the most promising veins, located at Trout Lake, is the San Juan mine, belonging to New York parties, and managed by D. W. Sisson. I mention this particularly, because it presents an example of what may be done by the exercise of watchful care and economy. Mr. Sisson has done more work with little money than nine tenths of the managers of this country, and has placed his mine upon an enviable footing.

Next season, we shall have good reports from many other localities. I predict good things from Bear Creek, Round Mountain, and new spots on Red Mountain.

SILVERTON, COLO., Dec. 18. THEODORE B. COMSTOCK.

SUMMIT COUNTY.

ROBINSON CONSOLIDATED.—A heavy verdict has been recovered by a former manager of this company. It seems that in May, 1882, L. B. Parker leased of the Robinson Consolidated Mining Company all that portion of the Robinson mine above the fifth level for a period of one year, work to begin June 1st, and the company to receive 25 per cent royalty. Accordingly, on that day he commenced operations, and by July 1st had expended $5100 in repairs and development-work, in doing which a large and valuable body of mineral was discovered. News of this being received by the officers of the company in New York, they notified Mr. Parker that his lease was canceled. As he had complied with all its provisions, he went to New York and demanded an explanation. An agreement was entered into that Parker should be retained as manager of the property at a salary of $500 a month, receive $2000 in cash, and the company were to pay him the difference in value on 2000 shares of stock at any time he might demand it before May 1st, 1883, on condition that Parker should produce enough ore to enable the company to declare a dividend of $20,000 by October 15th, 1882. It was further agreed that Parker waived some of his claims against the company for their violation of the lease in the event of this agreement being strictly fulfilled. During October, Parker, having forwarded them the $20,000 demanded, and the stock having appreciated about ninety cents per share, he called for a settlement, which the company refused; also declining to pay the $2000 as agreed upon, and shortly afterward notifying him that his services as manager were no longer required. In January last, Parker brought suit against the company in the sum of $50,000. The suit was called for trial during the spring term of the District Court in Leadville. The Robinson Company not appearing, default was entered against them. The matter was submitted to a jury, which, after a few moments' deliberation, returned a verdict for $40,000 damages, and assessed the costs upon the company.

DAKOTA.

FATHER DE SMET.—The superintendent writes December 4th: I herewith inclose you express company's receipt for bar No. 172, containing 779¾ ounces gold, the result of the clean-up of the mill for last half of November, and making 1502·28 ounces for the month. This is a lighter shipment than usual for this time of the month, and is owing to running through a considerable quantity of low-grade ore coming from open cuts near the surface, where we are forming stopes. This new run is starting off better, and from indications in the mine will make a good showing for this month's work. I have begun an uprise in Cook's chamber, to connect through to the Justice open cut, which will be of great advantage in handling ore from latter place when completed. The south header, third level, shows an improvement in quality of the ore. The remainder of the mine is as usual. The report for the week ended December 7th shows ore extracted from first, second, and third levels 2160 tons; ore milled, 2100 tons.

PONCA.—At this mica mine, mica is found in large sheets, but that so far taken out is not of very good quality. The prospects are favorable for finding a large amount of good mica when the workings are advanced.

STAND-BY.—A partial clean-up was made, giving satisfactory results. Ten additional stamps will shortly be started up, making forty in all.

MAINE.

DOUGLAS.—At a meeting of the stockholders, held at Bangor recently, it was voted to authorize the treasurer to borrow not exceeding $30,000, and to issue the company's notes, payable in one year. Capt. Daniel Dunn has been appointed superintendent, and will now have charge of both the Stewart and Douglas mines. The report made by Captain Dunn states that the work done in the lowest workings shows an improved condition, and that the prospects of the property are very favorable in every respect.

STEWART.—At the annual meeting, the following officers were chosen for the ensuing year: President, F. M. Laughton; Treasurer, F. H. Williams; Secretary, John S. Jenness; Directors, F. M. Laughton, John S. Jenness, F. W. Hill, C. E. Hill, C. P. Wiggin, J. R. Bodwell, and F. H. Williams. At a subsequent meeting of the directors, an assessment of ten cents per share was levied, payable December 25th.

MEXICO.

Things have been at a stand-still at Pachuca, according to the correspondent of the Mexican *Financier*. At the San Nicolas mine, preparations have been made for the cross-cut to tap the big bonanza.

The new road to El Cristo mine, building by the Tellos, is approaching completion, and when built it will certainly be the finest in this district, and a great advantage to all the mines in that section.

The California mine has been taken back by the free shareholders once more. The Rosario Viejo mine, under its present able management, is picking up.

The Sombrerete Mining Company has been exempted from the payment of municipal taxes by act of the Legislature of Zacatecas.

The news from Zacatecas is of an exceptionally good character. The Veta Negra has been pumped out to a depth of 800 feet, with enough ore disclosed, of from $50 to $80 a ton, or more, to warrant the company a surplus of over $1,000,000, over and above all expenses to date—and these expenses have been very heavy, it is said nearly $1,000,000.

The number of mining operators going into Chihuahua is exceptionally large, and many transfers of mining properties to American and English companies are in process of consummation.

The Jocuistita mine, of Sinaloa, was worked for the past three or four years on the best ore that could be found in it, and now only low-grade remains, which will last for several years, but from which no dividends may be expected legitimately.

MICHIGAN.

BEAUFORT.—Operations will be continued during the winter.

FRANKLIN.—The surplus as shown by an approximate statement made at the meeting of the directors held recently is $271,745.

HYDRAULIC POWER COMPANY.—The machinery on the Menominee River has been started up for the first time, and every thing was found to work smoothly and satisfactorily. The works will begin to furnish power for the Chapin and Ludington mines early in he new year.

IRON RIVER.—The force has been reduced to 75 men, and these are principally employed in sinking, and to a limited extent, preparing ground for future work. The management does not regard the outlook for next season as a very promising one, and for that reason will not mine any considerable quantity of ore until positively assured of a market at remunerative prices.

IRON STAR.—The new Iron Star Mining Company recently referred to, says the Marquette *Journal*, as having been organized in Detroit, appears simply to have been a reorganization of the Great Western Iron Company on a new and more substantial basis. The new organization is composed of men who have ample means with which to push the work of development, and the most of them being large consumers of ore, it will not be surprising should the Great Western come to the front with a largely increased product the coming year.

MICHIGAMME.—A new and apparently large body of ore has recently been struck in No. 4 shaft at this mine.

SAGINAW.—This company has begun explorations on the property on section 4, town 39, range 29, purchased last year from the executors of the Ingalls estate. The property in question adjoins the Saginaw mine on the east, and is deemed very valuable. A series of test-pits is sinking by the company and a churn-drill is also used in the work. The ledge has been reached in two pits. One of the pits encountered slates and the other limestone, and the work is now locating with the view of determining what lies between the two.

THURBER-BERRINGER.—The shaft at this gold and silver exploration is down between 40 and 50 feet, and in the bottom shows a vein a little over seven feet wide between well-defined walls. It is the intention to sink this shaft to a depth of 100 feet.

MONTANA.

LEWIS & CLARKE COUNTY.

Montana papers have been for the past few weeks discussing the question of the proposed establishment of extensive reduction-works at St. Paul, Minn., for the treatment of Montana ores. A number of prominent mining men in Helena have been interviewed on this subject, and they all unanimously oppose such a project. Naturally, for such works can as well be erected in Helena, which is surrounded by a number of mines that only need development and a market for the ores. Statements show that wood, water, iron ore, and limestone are plentiful and convenient. Coke (English) can be laid down for about $21 per ton, shipped by way of Portland. Pittsburg coke costs at Salt Lake $27 per ton, and as it will cost very nearly as much at St. Paul. Another point to be considered is, that St. Paul would have to haul fluxes, in many cases, hundreds of miles, while Helena has them almost at her very door. The only thing that would be cheaper at St. Paul is labor.

SILVER BOW COUNTY.

ALICE.—The directors are reported to be preparing a financial statement of the company's affairs, which, they hope, will prove amply satisfactory to the inquiring and dissatisfied stockholders who are threatening to make some trouble.

BELL.—An ore-body of high grade has been discovered. Its width is reliably reported to be eight feet. It occurs as a massive copper sulphide assaying from 50 to 76 per cent of that metal, much of it being a pure copper glance. Thus far, the silver assays have averaged $65, though samples of ore of high grade in silver have been put through the assay furnace.

COLUSA.—Operations are active in the 400-foot level of the Colusa. The ledge has been penetrated, and an extensive body of low-grade copper ore is reported. Further exploration will doubtless show the mine to be more productive at the increased depth lately attained. It is estimated that the upper levels contain enough ore to supply the smelter for two years.

MOULTON.—The important strike made some time ago from the 400-foot level holds its own in good shape. Explorations in good ore are active.

Digitized by Google

NEVADA.

ESMERALDA COUNTY.

MOUNT DIABLO.—A most elaborate report was presented at the annual meeting held in San Francisco recently. Extracts from it show that during the past year the greater portion of the labor has been directed to extraction of ore, and the result has been satisfactory. But little new work has been done during the year, except such as was necessary in developing the ore already found. The deepest stope that has thus far been worked in the mine is the stope below the third level, between winzes No. 1 and No. 2. This stope is 500 feet below the collar of the shaft, and about 160 feet west of it. There was considerable expense involved in working this stope, as the ore and waste had to be hoisted by a windlass 200 feet. Though this stope did not open very well, yet it yielded considerable $75 ore, with some of much higher grade, and every thing justifies the belief that further prospecting in this part of the mine will yield good results. Work at the other levels, winzes, drifts, etc., shows good prospects. A small body of sulphurets was found above No. 4 winze, between the 2d and 3d levels, that yielded 125 tons of sulphurets assaying $200 a ton. This body was in hard rock, and no such amount of sulphurets has been found elsewhere in the mine. Various plans to open the mine 200 feet deeper than the present workings, or 740 feet below the level of the collar of our shaft, have been discussed, but nothing definite has been decided on. Another financial question that may come up in the near future is in relation to milling facilities. Owing to the recent legal developments in this district and the chaotic state of affairs at present, it may be found necessary in the future to acquire a mill of our own, and it would seem advisable, at any rate, to so arrange that we should be somewhat independent in the matter. The leaching process that is soon to be in operation at the works of the Mount Cory Mill and Mining Company in Hawthorne might enable us to get a higher percentage from our lower grade ores than we are now obtaining by the process we are using, and at no greater cost. It is further stated that the following year will necessarily be a very expensive one, but from the experience of the past year and from the present outlook at the mine, there is every reason to believe that the results of the expenditure of the money will be satisfactory to all concerned.

	Tons.
The statement of ore shows ore on hand November 30th, 1883	400
Ore extracted during the year	8,027
Low-grade ore shipped to mill this year, but extracted in former years.	375

Discount, estimated at 17½ per cent	8,130.65—	38,330.22
Total surplus		$88,626.86

The following is a statement of the principal materials used at the mine during the past year, and the quantity now on hand:

No. 2 Hercules powder, 11,850 pounds; crystal wax candles, 12,680 pounds; fuse (D. T.), 80,250 feet; triple force caps, 41,650; coal oil, 262½ gallons; wood, 142 cords; charcoal, 2041 bushels; coke, 7000 pounds; lumber, 32,738 feet; water, 100,000 gallons.

LINCOLN COUNTY.

BRISTOL.—The troubles of this company will soon be settled, and the company will resume operations at an early day. The company's mines contain large quantities of low-grade rock, which will average $30 in silver. This ore is rebellious, but the company now has a process by which it can be worked to an advantage.

DAY.—The furnace at Bristol is undergoing a thorough overhauling at present, so that when it starts running there will be no cause for stopping. The bins are filled with coal and the teams are steadily hauling ore.

STOREY COUNTY—COMSTOCK LODE.

ALTA.—The water has all been taken out, and operations on the 2150 level have been resumed.

CHOLLAR-NORCROSS-SAVAGE.—The new hydraulic pump at this shaft will start up, and will give new life to all the middle mines.

DELAWARE TUNNEL.—Colonel J. B. Bissell and Mr. J. C. Langhorne, from Leadville, have recently inspected the progress of this tunnel. This is a prospecting enterprise, backed principally by Leadville people, and prosecuted in search of the northern extension of the Comstock lode. The tunnel at present has a length of 2800 feet, has already cut several seams of mineral in porphyry, and is daily expected to pierce the east country-rock and encounter the ledge. Another assessment has been collected, which will suffice to continue the work to a successful issue. The appearances of the ground at the head of the tunnel indicate the near approach to mineral.

GOULD & CURRY.—During the past year, the work has been confined to the 2500 level, according to the report presented at the annual meeting in San Francisco. On this level, five drifts or cross-cuts were run, aggregating in length 2040 feet. At the Bonner shaft, the machinery is overhauled and repairs are making to the main hoisting-works building, preparatory to putting the shaft in good order for the purpose of opening some ground on the old levels, which in the hurry to obtain depth was left unexplored. The above fact we mentioned in the JOURNAL some weeks ago; but since it seems to be a most important item in the annual report, we repeat it. The financial statement shows:

RECEIPTS.

General expenses	8,438.07—	$149,131.44

KENTUCK.—The report presented at the annual meeting in San Francisco shows that during the year $26,857 have been realized by the company, of which sum $23,980 have been paid in dividends to the stockholders. The yield was largely increased by the discovery of a body of ore on the 240 level, referred to in the last annual report. By a singular coincidence, it came to, but did not extend beyond, the north or south lines of claim, extending 30 feet above and 40 feet below the 240 level. A summary shows that 366 feet of winzes have been sunk, 1084 feet of new drifts and old ones reopened and timbered. At present, there are 12 floors of filling between the 434 and 240 levels, of an average thickness of 50 feet, which is the resource in sight from which to draw pay ore, and it is reasonable to suppose they will supply 50 tons per day for six months, of a grade much below the rate per ton realized the past year, yet affording a good revenue to the company, and, with increased reduction contemplated, partly making up the loss in value. Encroachments upon the company's claim, attempted by the Original Gold Hill Gold and Silver Mining Company, have been resisted and defeated, and the application for United States patent, which has slumbered for many years, has been revived, prosecuted, and is in a fair way to be secured. The directors renewed for one year, and until annulled by a future board of directors, the contract with C. C. Stevenson, under which he pays the taxes, the Sutro Tunnel royalty, all costs of extraction, and pays to the Kentuck Company a sum per annum graded according to the yield of the ore. It is a plan under which the company is always certain to receive some revenue without risk or expense.

OPHIR.—The result of the recent election seems to have been very satisfactory to the people at Virginia City. It is stated that there was a very lively demonstration at that place by the "deep miners," as they call themselves. They had huge bonfires blazing at various places. This seems to have been only a miners' celebration; for not a mining officer was seen. The annual report presented at the meeting shows that there have been extracted from the mine 3878 tons and 1810 pounds of ore, which have yielded $36,607.34, or at the rate of $9.44 per ton, being about 60 per cent of the assay value of the ore, it being very loose. No allowance has been made for moisture. This ore has been taken from above the level of the old Central tunnel. The work on the 1600, 1700, 1900, 2000, 2300, 2500, and 2700 levels has been confined to keeping the various drifts and connecting winzes in proper repair, necessary to the maintenance of the system of drainage and ventilation. To facilitate the extraction of the low-grade ore left in the old workings near the surface, the old Central tunnel, which was run in near our south line in the year 1882, cutting the vein at a point about 150 feet below the collar of the old Mexican shaft, has been cleaned out and thoroughly retimbered. The old drifts and winzes about that level have also been repaired. Owing to the want of the necessary ventilation in the lower levels (which deficiency will be remedied soon), the work for the last few months has been confined to explorations for ore near the surface. The returns from this portion of the mine so far have been unsatisfactory, but further explorations may give better results. The purchase of the Morgan mill property will enable the company to work low-grade ore that it would otherwise be unable to extract without loss. When the main north lateral drift on the 3100 level between the Ophir-Mexican and the Sierra Nevada-Union Consolidated winze is completed, the explorations of the 3100 level should be resumed, as the late developments in the Mexican ground have demonstrated the fact that the vein through which the Ophir-Mexican winze was sunk is continuous and strong down to this point, indicating that something of value may be found in further explorations.

The statement of the receipts and disbursements for the fiscal year ended November 30th, 1883, shows:

RECEIPTS.

To balance from last yearly report	$3,336.37
From sundry mines for labor	58,347.00
From sundry mines for supplies, etc	34,015.83
From sundry mines for office expenses	75.05
Sundry drafts on president	297,353.56
Total	$393,027.81

DISBURSEMENTS.

Salaries and wages	$167,985.16
Supplies and miscellaneous expenses	155,674.35
Milling	25,995.64
Sutro Tunnel, royalty on ore	1,944.35
Morgan mill expense	29 377.54
General expenses	12,833.09
	$392,810.13
Balance, cash on hand	817.68
Total	$393,627.81
Gross expense	$392,810.13
Received from other mines	92,937.88
Net expenses	$209,872.25

WHITE PINE COUNTY.

CRESCENT & EAGLE.—It is stated that a sixty-stamp mill will be erected at the mine. It is said that there are thousands of tons of $12 quartz in sight.

OSCEOLA.—The mill has begun crushing ore. The company has about 1500 tons of ore on the dumps ready for shipment, and is taking out about 30 tons daily. It will probably increase its force shortly.

NEW MEXICO.

GRANT COUNTY.

BLUE BELL.—Rumor states that this mine, situated at Bullard's Peak, has been sold for $12,000. This is the mine that first brought this camp into prominence; but the owners, having so much in hand, have neglected it, doing nothing more on it than the annual assessment-work. Work is to be pushed vigorously.

SAN MIGUEL COUNTY.

The recent gold discoveries in the vicinity of Las Vegas have created great excitement. Probably the reports are exaggerated. They state that gold has been found in paying quantities in a lot at the hot springs, owned by a prominent resident of Topeka. The hills and valleys around Vegas are all swarming with excited gold-seekers, many of whom meet with success. A company has been formed, and will develop some claims. A few years ago, Elizabethtown, near Las Vegas, had a population of five thousand gold miners, and for a number of years a company engaged in hydraulic mining has taken out fifty thousand dollars annually. Some Colorado capitalists are already on the ground investigating the extent and richness of the deposits.

PENNSYLVANIA.

SUNBURY SMELTING-WORKS.—At a meeting of stockholders, at Sunbury, held December 24th, Manager Kidney made an official report that the company was embarrassed, and that $75,000 are needed to place it on a sound basis.

UTAH.

BOX ELDER COUNTY.

The lead mine at Bingham is sending out some fine ore. A big strike was made in the west drift a short time ago, of a large body of free-milling ore. A shipment of 60 tons made last week sampled 57 ounces silver and no lead. The mine is shipping 15 tons of first-class ore per day.

Digitized by Google

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Dec. 28.

The mining market was exceedingly dull this week, owing to the Exchange being closed on Monday and Tuesday being a holiday, and but for the default of a broker on his contracts the market would have been lifeless. On Wednesday, it was announced that Mr. C. S. Benham had disappeared, and had failed to meet his contracts. Large blocks of the stock of Harlem and Sonora Consolidated were sold out on his account under the rule, and the prices of these stocks were forced down to a very low figure. Harlem declined from $1.15 last week to 17c., and Sonora from 22c. to 8c. It is said that Mr. Benham has left for the West, owing members of the Exchange a large amount of money on contracts. Bodie Consolidated sold at a very high figure to-day, through manipulation. This stock has been quite strong on the San Francisco market for the past few days. Amie was very actively dealt in to-day at weak prices. Below will be found a complete summary of the market. The total number of shares sold aggregates 151,146 shares, as against 94,335 last week.

The Comstock shares were very quiet, at steady prices. California sold at 12c., and Consolidated Virginia at 32c. Sierra Nevada was quiet and steady, selling from $3.40@$3.50. Best & Belcher sold at $2.50 with one small transaction. Sutro Tunnel was quiet and steady, selling at 17c.

The Leadville stocks were quiet at irregular prices. Amie was very active to-day, and sold at weak prices; it ranged between 9@7c., the transactions aggregating 15,700 shares. Chrysolite was moderately dealt in at irregular prices, selling from $1.30@$1.25. Iron Silver was also irregular, with a fair business; it sold from $2.20@$2.05@$2.10. Little Chief was quiet and steady at 56@58c.

In the Bodie stocks, Bodie Consolidated was quite strong to-day, in sympathy with the San Francisco market. The company levied an assessment of fifty cents a share last week, making a total of one dollar per share levied within six months. The stock sold on this market from 85@65c. during the week, and from 70c.@$1.50 to-day, closing at $1.45. Standard was quiet, selling from $6@$5.75. Bulwer was quiet at 45c.

In the Tuscarora stocks, Navajo was quiet at $3.60 and Elko Consolidated records one transaction at 17c.

In the miscellaneous list, Alice was weak, with a small business, selling from $2.60@$2.25. Caribou sold at 7c. Green Mountain was strong, with a small business, selling from $1.35@$1.50. The tunnel, which is advancing at the rate of 60 feet a week, has reached the zone of barren quartz found in higher levels. The prospects are considered very favorable. The chief buyers of the stock are in siders.

Homestake was quiet and steady at $10. Horn-Silver was irregular, with a moderate business, selling from $6.38@$6.50@$6.25. Northern Belle was quiet and weak, selling at 65c. assessment paid, and from 25@18c. assessment unpaid. Robinson Consolidated was quiet and steady at 30@31c. Sierra Grande records one transaction at 60c.

Barcelona was weak, under a small business, selling from 20@13c. Bradshaw was quiet and steady, selling from 11@17c. Eastern Oregon was weak, with a very small business, selling at 10c. Harlem suffered a very strong decline; it sold from 25@9@14c., with an active business. Sonora Consolidated was very active and very weak, selling from 22@8@10c., with a business of 97,600 shares.

MEETINGS.

The Arizona Consolidated Mill and Mining Company, Metropolitan Hotel, New York City. Annual meeting of stockholders and election of trustees, January 7th, at twelve o'clock M.

The Gold Cup Mining and Smelting Company, No. 89 Water street, New York City. Annual meeting of stockholders and election of trustees, January 8th, from twelve to two o'clock P.M.

DIVIDENDS.

The Franklin Mining Company, of Michigan, has declared a dividend of two dollars per share, payable January 1st to stockholders of record December 22d.

The Iron Silver Mining Company, of Colorado, has declared a dividend (No. 13) of twenty cents per share, payable January 9th.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway, report as follows for the past week:

The fluctuations of the past week have been between $1.14⅛ and $1.13, which means almost total stagnation. Monday, the Exchanges all closed and Tuesday was a holiday, and this fact served to prevent trading. The market to-day (Friday) is very much like Friday of last week, both in the range of prices and dullness. It is not likely that the market will resume its old-time activity till New Year's is passed. Refined is firm at 9¼.

On Saturday last, the two Oil Exchanges balloted on the question of consolidation. The members of the New York Mining Stock and National Petroleum Exchange voted in favor of consolidation by a large majority, but the members of the New York Petroleum Exchange were considerably excited over the question, and a close vote was the result. It was carried, however, the vote standing 269 in favor and 250 against the consolidation, 169 not voting. There was considerable dissatisfaction expressed by the minority, who claimed that this vote did not show that the Exchange was in favor of consolidation. A joint committee has been appointed by both Exchanges to prepare a new constitution, and this must be ratified by both before the consolidation can be finally effected.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Dec. 22.....	$1.13⅝	$1.14⅝	$1.13¼	$1.14⅝	3,592,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, December 27.

Owing to illness, your correspondent was unable to send you a review of the market last week, and will endeavor now to give a *résumé* of the past two weeks. The most important item of interest is the fact that the stockholders of the Franklin Mining Company have at last received their first dividend of $2 a share. At the annual meeting, the report of the directors showed that on December 1st the company had a surplus of assets of $271,754.02, from which it was voted to pay the dividend of $2 per share on 40,000 shares—$80,000—leaving a balance of over $190,000 on hand. When the present management of the company took the property from the tributers, there was no ore in sight, and the mill was a wreck. There were $16,000 in the treasury, however, and that sum has been increased as shown above without calling upon the stockholders for any thing, and the output has been increased from what was considered an impossible 40 tons per month to 200 tons. The lower levels of the mine are now reported richer than ever before in the history of the property. The stock has been very firm at $11¾@$12, with quite an active demand, the last sale being at $10, ex dividend. Calumet & Hecla has ruled steady, but not particularly active, at $239@$238¼, the last quotation being the price to-day. Quincy has dragged heavily and declined from $49¼@$46, but has rallied somewhat, the last sale being at $48 for one share only. Osceola sold at $17½, ex dividend, and a sale of Atlantic at $10 shows an advance of $1 over last sale. Pewabic was heavy, and declined from $3@$2 per share, at which price it is now offered. Huron advanced from $1@$1 9-16, with sales of 600 shares. The reports from the mine are encouraging.

In silver stocks, there has been but little activity and no special feature. Bonanza sold at $1¼, a decline of $\frac{3}{16}$. Silver Islet sold at $3, same as before. Catalpa, at 30c. Sullivan sold at $\frac{1}{2}$; but at the Mining Exchange, sales are reported as high as $1.12½ regular and $1.17½, buyer 60, with later sales at $1.05, buyer 60. Bowman Silver has declined to 7c. Empire, steady at about 25c. Dunkin, 27@28c. regular, and 30c., buyer 30. Massachusetts & New Mexico has been assessed again, this time 10c. per share, and there is no market for the stock. On the whole, the outlook for mining stocks in this market is not very encouraging to holders.

These was no feature of interest this afternoon, the market closing tame and lifeless.

BULLION MARKET.

NEW YORK, Friday Evening, Dec. 28.

The London silver market has shown great firmness the present week, and rates here have advanced as per accompanying table:

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
Dec. 22	50 15-16	110⅝	Dec. 26	50 15-16	*
24	50 15-16	110½	27	50 15-16	110⅝
25	Holiday.	.....	28	51	110¾

*110⅝@110½.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended December 28th, as compiled from various sources, amounted to $81,000, as against $119,000 reported for the previous week. The receipts from January 1st, 1883, to date are $11,226,321.

Foreign Bank Statement.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 3 per cent. During the week, the bank lost £532,000 bullion, and the proportion of its reserve to its liabilities was reduced from 43 1/16 to 39 13/16 per cent, against 36 1/16 per cent at this date last year. December 27th, the bank lost £153,000 bullion on balance. The weekly statement of the Bank of France shows a decrease of 1,900,000 francs gold and a decrease of 1,050,000 francs silver. The Imperial Bank of Germany lost specie to the amount of 10,320,000 marks.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver

Digitized by Google

bullion, should be diminished by about 14½ per cent, to arrive at actual value.

METALS.

NEW YORK, Friday Evening, Dec. 28.

Copper.—Business is restricted to narrow limits. The offerings of outside lots of Lake at 14⅞c. have ceased, and it would probably be a difficult matter to obtain any Lake at less than 15c. On the other hand, the past month has not been a very active one for manufacturers and there are evidences of a falling off in the consumption. So far as outside brands are concerned, refiners complain of a scarcity of raw material, the sources of supply from which it is drawn being less prolific than formerly. The great increase in the production has been in Montana, but directly and indirectly the greater part of the output of the mines and works at Butte City goes abroad.

We quote outside brands, according to quality, 14@14¼c. England cables £57 for Chili Bars and £64 for Best Selected.

Tin.—This metal has somewhat improved, under a light business, 19@19⅛c. being asked for Straits spot, large lines. London cables to-day, £83 2s. 6d.

Lead.—Outside of a few small car-lots which have changed hands, absolutely nothing has been done. Holders maintain their attitude of firmness without having as yet impressed buyers much. The stand taken by some of the holders is represented to be due to the fact that the lead they have on hand has cost them more than they can now get for it. It certainly would do them no good to attempt to force it on a reluctant market. So far as Common is concerned, the future depends very much upon whether there will be an open winter, encouraging to the building trade, which at this season is its sole reliance, the shot trade being practically over. It is likely that within the next few weeks, should holders remain firm, a number of buyers will be forced to take lead at the figure asked. This does not, however, affect the general situation, and should not therefore give rise to any undue hopes.

Messrs. John Wahl & Co., of St. Louis, telegraph to us as follows to-day:

Our market is quiet and dull, with prices unchanged. We quote Refined 3·30c., and Common at the same figure.

Spelter.—There is nothing to report. The market drags along at 4⅝@4¾c., with occasional lots offered at a slight concession. Silesian is nominally 5⅞c.

Antimony.—In sympathy with foreign advices, antimony is firmer, being quoted 11¼c. for Cookson's and 10¼c. for Hallett's.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Dec. 28.

American Pig.—Some of the furnace companies report a fair business and are booking orders in round lots. The impression seems to prevail that prices are as low as it is possible without entailing a heavy loss upon many of the producers. Some of them are out of the race, and others are expected to fall off at an early date. On the other hand, the general reduction of wages so quietly submitted to seems to point to the possibility of lower figures, should sellers become urgent. It is true, however, that stocks are decreasing in producers' hands, and that there are very few weak concerns left. The market is steady, furnacemen showing considerable firmness. We quote Foundry, No. 1, $20@$22.50; No. 2, $18.50@$19.50; and Gray Forge, $17.50@$19, all at tide-water. There has been a little more activity in Bessemer pig at the range of $20@$20.25. We hear of a sale of 5000 tons of Spiegeleisen at about $28.50. This morning, the *Tribune*, the *Times*, and other daily newspapers erroneously stated in a special dispatch that an injunction had been granted against the New Jersey Zinc and Iron Company. The fact in the case is, that the injunction is in favor of the New Jersey Zinc and Iron Company against Trotter.

There have been no transactions in iron at the Metal Exchange this week.

Scotch Pig.—The market is dull, the arrivals being light, and the sales chiefly to arrive.

We quote ex ship and to arrive: Coltness, $22@$23; Langloan, $22.50@$23; Summerlee, $22.50; Eglinton, $20@$20.50; and Dalmellington, $20@$20.50.

At the Exchange, the following cable quotations were received to-day: Coltness, 55s.; Langloan, 53s. 6d.; Summerlee, 52s. 6d.; Gartsherrie, 50s. 6d.; Eglinton, at Ardrossan, 45s. 3d.; and Dalmellington, 47s. 6d.

Steel Rails.—There has been some activity, due principally to the fact that, under exceptional circumstances, some sales were made at a low figure, the whole aggregating 30,000 tons for winter delivery. It appears that the contract at Chicago led to some concessions by some of the mills engaged in it on Eastern business also. This in time involved others who had stood aloof until now. There have since been very exaggerated rumors concerning mythical transactions, while the actual concession made was a little more than $1 below current market quotations.

Old Rails.—There is nothing doing. We quote $22@$22.50 for Ts.

Philadelphia. December 27.

Three or four large consumers of pig-iron, who have been fortunate enough to place contracts for large lots of forge and foundry iron at very low rates for next year's delivery, are very certain that lowest prices have been reached, and that an upward tendency will be developed within a short time; but, so far as can be ascertained, this opinion is not generally entertained, and most buyers are satisfied that it is safe to continue to buy in small lots, and that they will be able to buy to as good advantage during the winter as at present. There are some inquiries in hand today for special brands of foundry. There is a little more firmness in standard brands, and less anxiety to cut prices, owing to the expectation of an active demand in January. Should this active demand not be developed, a further weakness is quite probable. Considering the condition of stocks in consumers' hands, it seems quite probable that the demand will be sufficient to enable makers to hold rates with more firmness than during November. Inferior brands are still weak. Forge sells this week at $17.50@$18. There are inquiries for Southern irons at $18. Very few orders have yet been placed, but there is demand for all that can be had. Standard Forge ranges from $18@$19, with $18.50 as a fair average for a good make. The talk among brokers is, that the demand must improve during January, considering the indifferent demand for the past sixty days. For Foundry irons, prices range from $18.50 for No. 2, to $21 for No. 1, with $19 and $20.50 as the average selling prices.

Foreign Irons.—The only large sale of Bessemer Pig was one lot of 5000 tons at $20, tide-water. Several other lots are wanted. Spiegeleisen is also inquired for freely, and in a few days sales will be announced.

Muck Bars.—Quotations are given at $32@$32.50—no sales.

Blooms.—Quotations, $46@$47 for Anthracite, and $55@$57 for Charcoal.

Merchant Iron.—The competition in the finished iron trade has put the ruling prices very low. A number of inquiries have been presented during the holidays. Two or three manufacturers are confident of selling a month's output in a few days. Quotations, 2c. for Refined, and 1·75c. for Common. Bids in hand are at 1·80@1·90c., and some buyers expect to place orders for Refined at 1·80c., and for Common at 1·60c. The Thomas Iron Company has reduced wages 10 per cent.

Nails.—Jobbing demand is light. Quotations nominally $2.45@$2.55. Offers are in hand at $2.35. The six weeks' suspension in Western mills begins on Monday, and is expected to help the Eastern trade.

Plate and Tank Iron.—There is a little more inquiry in hand, but no large orders are to be expected until January.

Structural Iron.—Mills are closing up large orders, and are anxious to secure the business which has been in sight for a long time. Quotations are unchanged.

Steel Rails.—Makers quote $35 firm to-day, but are not able to say much as to February business. They assert that there is less pressure in a downward direction than a few weeks ago, and that buyers will come forward and buy at present prices.

Old Rails.—For Tees, $23 is asked, and $25 for Bridge Rails. For Double Heads, $25 is wanted for shipment. In the absence of business, it is impossible to give selling prices.

Scrap-Iron.—For cargo lots, $22 is asked. Crop-Ends are offered at $22. No. 1 Scrap, $22.50@$24. Very little doing.

Pittsburg. December 27.

To-day's quotations in crude iron are from $16.50@$16.75 for White and Mottled. Neutral, Lake ore, $17. Gray Forge, $17@$17.50. Foundry, $19.50@$21.50. The week's transactions have not been up to the average. It is impossible to determine the outlook with any degree of certainty. Good arguments are given on both sides for very opposite views. The advantage is at present, and will for a long time to come probably be, with the buyers, and buyers are showing a corresponding indifference as to future requirements. An occasional large lot of forge is sold, but most of the business is in from 25 to 50-ton lots. So many mills have shut down that there is but little hope of any improvement in forge. Very little iron will be made between this and January 10th. Some few manufacturers look for a very active demand next month, and base their expectations upon the fact that business for the last few weeks has been below the average, and that stocks in consumers' hands are light. The suspension to begin on the 19th has already had some influence on the shading of nail quotations. The lowest figures heard of are $2.30, although it is said that sales have been made at less. Old rails are under fair inquiry. No sales of importance have taken place. For prompt delivery, $24 is asked; $23@$23.50 offered for late delivery. The movement in steel rails is without any interest. Quotations, $34@$35. Track supplies are in better request. Spikes are in fairly active demand at $2.50. Other small railroad material is moving slowly. Crop-Ends, $23@$23.50 for American. Movements in scrap are without interest.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Dec. 28.

Anthracite.

The trade is naturally quiet during holiday week and just before the end of the year, when nobody cares to order fresh supplies, especially on what buyers consider a declining market. The stocks afloat and in cars here are not so heavy as they have been, and a better feeling might develop if the companies took prompt action. It seems to-day that a decision concerning the policy during the next three months will soon be reached—either to-morrow or Monday next. The matter is certainly being thoroughly canvassed, and it is understood that a plan has been submitted looking to a cessation of more than thirty days during the next three months, to include, possibly, two full weeks of stoppage, the rest to be three-day work for a number of weeks. This probably would give tone to the market, which is now dull.

Mr. John H. Jones, official accountant, has issued the following statement of the anthracite coal tonnage for the month of November, 1883, compared with the same period last year, which includes the entire production of anthracite coal, excepting that consumed by employés, and for steam and heating purposes about the mines:

	Nov., 1883.	For year 1883.	For year 1882.	Difference.
Phila. & Reading RR.	1,242,399	9,732,085	6,355,690	I. 3,376,395
Central RR. of N. J.	*.....	1,745,399	3,862,703	D. 2,117,304
Lehigh Valley RR.	†623,843	5,849,307	5,408,808	I. 440,499
Del., Lack. & W. RR.	489,769	4,708,419	4,230,067	I. 478,352
Del. & Hud. Canal Co.	‡378,634	3,288,977	2,906,848	I. 382,128
Penna. RR.	268,838	2,557,625	2,169,601	I. 388,024
Pa. Coal Co.	155,488	1,432,170	1,344,544	I. 87,626
N. Y., L. E. & W. RR.	39,122	345,904	242,394	I. 103,510
Total.	3,198,094	29,659,886	26,520,656	I. 3,139,230

* Included in tonnage of the Philadelphia & Reading Railroad.

† This amount includes the production of the mines of the State Line & Sullivan Railroad Company, amounting to 8000 tons.

‡ In addition, there were 59,024 tons transported from the mines by the Delaware & Hudson Canal Company, during October, which are included in the tonnage of other interests.

The stock of coal on hand at tide-water shipping points, November 30th, 1883, was 696,380 tons; on October 31st, 1883, 604,865 tons; increase, 91,515 tons.

Bituminous.

There is practically nothing to report. Orders are scarce, and prices are correspondingly unsettled.

Buffalo.

The great cantilever bridge at Niagara Falls, 910 feet in length, was tested and formally opened last Thursday, December 20th. It is a triumph of engineering skill and a marvel of rapid construction. From eight to ten thousand persons were present. The testing train was estimated to weigh 1900 tons; composed of 20 locomotives and 24 flat-cars heavily loaded with ballast, and so divided that one half moved up one track and the remainder on the other. The bridge is 239 feet above the river to the base of the railroad track, and the clear span across the river is 495 feet. The weight of the bridge itself is 3000 tons.

The New York Central & Hudson River Railroad Company owns $320,287.33 in stock of the Morris Run Coal and Mining Company. The movement of coal over this road for 1882-83, as compared with 1881-82, shows a falling off—exact figures not stated.

The American Midland is the last mystery in the railroad world. It is rumored that, with sundry connections, it will tap the coal-fields of Pennsylvania on its way to connect with the West Shore Railroad to New York. Its Western terminus is at Fort Wayne, Indiana. The Buffalo *Courier*, which keeps its readers well posted on railroad matters, says: "Incidentally, it may be remarked that Fort Wayne, being the starting-point, is of considerable significance, for argument's sake if nothing else, because it brings the American Midland into direct and important connection with the Gould system. Again, this becomes of still greater importance upon the supposition that the survey now making from Red Bank, at the mouth of Red Bank Creek and at the junction of the low-grade with the river division of the Alleghany Valley, is in the same interest as that which projected the American Midland. The engineers have fifty miles located of this line on the opposite side of the creek, paralleling the low-grade of the Alleghany Valley. An examination of the map shows that, if this parallel is continued to Driftwood and so on eastward through the anthracite coal region, it will bring it to a connection with the Lackawanna at Scranton, or, still farther east, with the West Shore at Middletown, thus establishing a new and great trunk line between New York and Chicago. From the numerous proposals that the West Shore has had to take its business West, and from the comparative indifference it has exhibited with respect to the selection of a route, it is only fair to presume that it is interested in this new line, or that there is at least some understanding between its backers and Jay Gould."

The question of a reciprocity treaty with Canada is again talked about by our citizens. There are earnest advocates for as well as against a measure looking to the settlement of this long-discussed matter. As far as we are concerned, as a border city and a friendly neighbor, a reciprocity treaty would have a large vote in its favor, if wisely drawn.

Horsford's Acid Phosphate.

Well Pleased.

Dr. C. ROBERTS, Winchester, Ill., says: "I have used it with entire satisfaction in cases of debility from age or overwork, and in inebriates and dyspeptics, and am well pleased with its effects."

MINING MACHINERY

INCLUDING

Steel Water Jacket Smelting Furnace,

Quartz Mills, Concentration Works, Hoisting Apparatus, and all classes of Machinery employed in Mining and Reduction of Ores.

PORTABLE AND STATIONARY

STEAM ENGINES

From Ten to Two Hundred Horse Power, Steam Boilers of any Style and Capacity.

SAW MILLS

Adapted to the wants of the Planter, Miner, or for the manufacture of Merchant Lumber, Prices ranging from

$200

Upwards, and of Capacity from 2,000 to 50,000 Feet per day. Shaftings, Hangers, Pulleys, Gearing, and all Appliances for the Transmission of Power.

LANE & BODLEY CO., Cincinnati,

Western Office: ... First South St., Salt Lake City, JOSEPH M. BOOKS, C.E., M.E., etc., Consulting Engineer. ☞ *Treatise on Smelting and other Circulars sent Free.*

Sole Manufacturers of the Bruckner Revolving Furnace.

J. PRENTICE & SON 91 & 93 B'WAY, N.Y. EST'D 1842

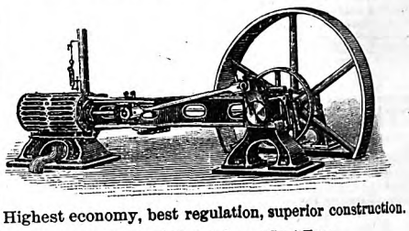
Transits, Levels, Compasses, Rods, Chains, Tapes, Altitude Barometers, Air Meters, Drawing Instruments, etc.

In every variety of *superior* quality and at *de facto* reduced prices.

Send for, and specify, 192 page E. & M. J. Catalogue.

HAMILTON WORKS,

Youngstown, O.



To MECHANICAL AND MINING ENGINEERS. Our plant and tools are modern. We employ first-class mechanics only, and are prepared to execute work of any size or character promptly.

Estimates furnished from Drawings and Specifications.

Ordinary-sized ENGINES, SHAFTING, HANGERS, etc., carried in stock.

WM. TOD & CO., Founders and Machinists.

BUCKEYE AUTOMATIC

Highest economy, best regulation, superior construction.

Illustrated Catalogue Sent Free.

Buckeye Engine Co., Salem, Ohio.

Eastern Sales Agency Offices: No. 69 Astor House, New York, and No. 53 Mason's Building, Boston.

GEO. A. BARNARD, Manager.

For Mining Purposes address W. H. H. Bowers, 35 Wall Street, New York.

DIVIDENDS.

OFFICE OF THE IRON SILVER MINING COMPANY, 12 Wall Street,
NEW YORK, Dec. 22, 1883.

The trustees of this company have this day declared

DIVIDEND NO. 13,

of TWENTY CENTS per share, payable at this office on Wednesday, January 9th, 1884.

Transfer-books will be closed at three o'clock P.M., Wednesday, January 2d, and will be reopened on Thursday, January 10th.

HOMER A. HOIT, Secretary.

SAN FRANCISCO, Dec. 14, 1883.

THE FATHER DE SMET CONSOLIDATED GOLD MINING COMPANY has declared dividend No. 30, of TWENTY CENTS per share, payable at the office of Laidlaw & Co., 14 Wall Street, New York, 31st inst.

Transfer-books will close 22d inst.

H. DEAS, Secretary.

MAPS.

ARIZONA AND NEW MEXICO.—This map shows all the Township Surveys, Private Land Claims, Post-Offices, and Settlements. It also exhibits the Explorations of other Government and Private Expeditions, including the facts developed by the Surveys for the Routes of Projected Railroads, etc., 1881. Scale, one inch to thirty-three miles. Colored, 24×17 inches. Pocket form, $1.

COLORADO.—Topographical and Township Map of Part of the State, exhibiting the San Juan, Gunnison, and California Mining Regions. By Louis Nell. Substantially same as above. Post-offices, March 1st 1880. Scale, 1 inch: 9 miles, 1-570,240. Plain sheets for wall, 90 cents.

COLORADO.—Cannon's Map of the Mineral Belt of Colorado. Taken from the Records of the Surveyor-General's Office, and other reliable Official Sources. Showing, in colors, the Mineral Belt, Gold Districts, Silver Districts, Coal Districts, County Lines, and Boundaries of Land Districts. There are also given the Capital, County Seats, Township Lines, Railroads, and Projected Railroads. Scale, 1 inch: 10 miles. Size, 26×30 inches. Pocket form, $1.50; as a wall-map, $2.

SAN JUAN MINING REGION (COLO.).—Kibbe's Geographical and Geological Map of the San Juan Mining Region. 1881. Shows county lines, wagon-roads, stage routes, trails, railroads, cities and towns with post-offices, camps with post-offices, reduction-works, mountain peaks, continental divide. Also (by colors), eruptive rocks, Carboniferous, Cretaceous, Jura Trias. Elevations above sea-level. Scale, one half inch to the mile. 22×27 inches. Includes, on same sheet, a reduced Map of the State of Colorado. Printed in colors, with board covers. $1.50.
